PREFACE

WORKNG TOGETHER FOR OUR GLOBAL RANGELANDS FUTURE

2-6 June 2025, Adelaide, Australia.

Welcome to the XIIth International Rangeland Congress (IRC), being held in Adelaide, South Australia!

This Congress is the first opportunity for the international rangeland community to meet face-to-face since 2016 when the Xth IRC was held in Saskatoon, Canada. In 2021 due to ongoing COVID disruptions, the XIth IRC was held in Nairobi, Kenya as an online event.

We are thrilled to be welcoming more than 700 delegates from 46 countries to the XIIth IRC, to share knowledge, experiences and ideas that will progress the management of the 56% of the world land mass that is rangeland.

We have more than 60 delegates are participating in pre-Congress Tours arriving in Adelaide from Perth, Alice Springs, Longreach and Sydney. Three pre-Congress Workshops are also being attended by more than 150 delegates and nearly 200 delegates will be celebrating the Australian Rangeland Society's 50th Birthday.

Interest in and support for the Congress Program has been high. These Draft Proceedings contain over 400 papers, that will be delivered at the Congress as either full oral or lightning presentations or displayed as posters. The papers are grouped into the seven sub-themes for the Congress:

1. Valuing rangelands and pastoral systems for their societal contribution
2. Co-design, partnerships, and incorporating traditional knowledge for more enduring rangeland outcomes
3. Technology, information systems, communication, and big data to aid monitoring and decision making
4. Integrating rangeland ecology into management
5. Managing risk – climate and other system shocks and trends
6. Livestock production systems in a world of changing drivers
7. Multi-functional land use in rangelands – moving beyond niche opportunities

These sub-themes reflect the increasing inter-connectedness between what is happening in the rangelands and what is happening in the rest of the world's economies, social systems and governance. They also recognise the need to integrate trends in technology, artificial intelligence and communication into the day-to-day lives of rangeland decision makers and residents. Finally, for too long the traditional indigenous knowledge of long-established rangeland cultures has been ignored, but no longer.

We encourage you to absorb the information contained in the papers presented in the Proceedings and to expand your knowledge through your interactions with the 700 people who have gathered from all parts of the world to attend the Congress. By working together, we can build better, fairer and more beneficial rangelands for all of humanity to appreciate and cherish.

At the conclusion of the Congress, the Proceedings will be augmented with contributions from the keynote speakers, the three pre-Congress Workshops, and the various Panel sessions being held during the Congress.

The Chairs of the Organising Committee for the XIIth International Rangeland Congress from 2021 to 2025 acknowledge the tremendous contributions of Dr Sarah McDonald (Chair, Publications Sub-Committee) and her team of people who reviewed papers; and Dr Alex Baumber (Chair, Program Sub-Committee) and his team who sorted Abstracts and arranged the Program for the Congress. We offer our grateful thanks.

Pieter Conradie, Chair, Australian Organising Committee, 2021-2022;

Dr Nicole Spiegel and Dr Andrew Ash, Co-Chairs, Australian Organising Committee, 2022-2024;

Dr Cath Waters and Dr Don Burnside Co-Chairs, Australian Organising Committee, 2024-2025

TABLE OF CONTENTS

PLENARY PAPERS

Stewards of the steppe: Khoid Mogoin Gol-Teel pastoral community institutions and their role in rangeland ecosystem conservation

Ulambayar, T[1]; Nergui, M[2]; Batkhuyag, B[3]; Davaasuren, O[4]

[1,2]Zoological Society Luujin; [3]WWF Mongolia; [4]Bayanbulag CBO, Bulgan, Arkhangai

Key words: community-based conservation; pastoral institutions; conservation outcomes; Mongolia

Abstract

Rangelands, covering over 50% of the Earth's terrestrial surface and providing essential ecosystem services, are experiencing severe degradation due to land conversion, overgrazing, invasive species and unsustainable land-management practices exacerbated by climate change. This degradation contributes to biodiversity loss, with habitat loss, resource decline, pollution and fragmentation posing serious threats to human society, including economic losses and food insecurity. This case study offers a positive perspective on Mongolian herders and their collaborative efforts to protect natural resources vital for their livelihoods and cultural identity. The Khoid Mogoin Gol-Teel Local Protected Area (KMGT LPA) in Central Mongolia, home to iconic species such as musk deer and snow leopards, supports over 400 herder households with 90,000 livestock (NSO 2023). Since Mongolia’s transition to a market economy in the mid-1990s, the KMGT LPA has faced rangeland degradation and declines in wild species due to overgrazing and illegal activities. This study evaluates outcomes of initiatives of the Union of Conservation Communities (UCC) over the past five years, which have led to a significant increase in community engagement and participation, enhancing biodiversity conservation and improving herders’ wellbeing. Specifically, participation in conservation training rose from 9% to 72%, and reports of illegal poaching and logging dropped to zero, highlighting the effectiveness of UCC efforts. These findings contribute important insights to the discourse on sustainable rangeland management and community-based conservation (CBC) strategies, supporting global efforts to achieve the Sustainable Development Goals and to promote ecosystem stewardship.

Introduction

Rangelands occupy nearly 70% of Mongolia's total area, directly supporting the livelihoods of almost 300,000 herders and over 64 million livestock (NSO 2023). Since Mongolia's transition to the market economy, with the collapse of state cooperatives and privatisation of livestock, the national herd has tripled in the past three decades (NSO 2023). This rapid growth has contributed to rangeland degradation, affecting 58% of the country’s pastures (Densambuu et al. 2018) amidst intensifying climate change. In the absence of effective rangeland management institutions and because of weak governance over natural resources, Mongolia has witnessed a rise in illicit activities, including poaching, illegal logging and mining, which have depleted wild species and their habitats. Currently, only 21% of the country is under state protection, leaving vast rangeland ecosystems unprotected and heavily exploited, adversely impacting on Mongolia’s natural capital. In this context, CBC could play a pivotal role in empowering herder stewardship to address the management gap and sustain ecosystem services vital to Mongolians. Since the introduction of CBC in the late 1990s, Mongolia has experienced varied outcomes, with positive results often failing to endure in the long term. This study aims to contribute to the broader research question of the key factors for successful CBC.

The KMGT LPA, located in Bulgan District of Arkhangai Province, covers 243,000 ha of mountain forest-steppe, with nearly 20% covered by forests (44,830 ha) that support rich biodiversity, including globally endangered species such as musk deer, saker falcon, steppe eagle, red deer and Mongolian marmot. The LPA's accessibility from the Arkhangai Province centre and the main road to the western region has led to challenges like illegal logging, poaching, forest fires and overgrazing. In response to these issues, the Bulgan District Government declared KMGT an LPA in 2017, and the Union of Conservation Communities (UCC) was established to unite the LPA herders with support from the Zoological Society of London (ZSL). This study aims to evaluate the initiatives undertaken by the UCC over the past five years, focusing on how these efforts have sought to address the dual challenges of rangeland degradation and decline in biodiversity. By assessing both the social and the ecological outcomes of UCC initiatives, the study will contribute to identifying the key factors that foster successful community-based governance and sustainable rangeland management, thereby enriching the discourse on effective strategies for conservation in Mongolia.

Methods

The study analysed data from two reports produced by researchers at the Independent Research Institute of Mongolia (IRIM) in 2019 and 2024, focused on assessing socio-economic surveys as well as separate biodiversity monitoring reports for three key species. The IRIM study employed a mixed-methods approach to assess social and ecological outcomes of KMGT LPA management. Research instruments included social surveys designed to capture herders' perceptions, alongside observations of natural resource conditions and changes, livelihoods (encompassing primary income and expenditures), housing, access to financial services, attitudes and participation in conservation initiatives. To evaluate herders' wellbeing, the study used the Multidimensional Poverty Index (MPI) (Alkire & Foster 2011), which integrates two critical components: the incidence of poverty, representing the proportion of individuals experiencing multiple deprivations, and the intensity of those deprivations. Ecological outcomes were measured through assessments of forest and rangeland conditions and the population status of key wildlife species. This involved the use of transects for musk deer monitoring, bird surveys and marmot counting, supplemented by herders' observations and reported sightings. For monitoring poaching and timber-logging activities, secondary data sources, including records of the Arkhangai Environment & Tourism Department (ETD), were also analysed.

Results

Social outcomes

The initiatives undertaken by the UCC have led to significant social outcomes within the KMGT LPA, enhancing community engagement, participation and governance structures among herders.

Community institutions established and governance process laid out. The baseline report indicated the existence of six registered Forest User Groups (FUGs), each comprising 6–7 member households; however, these groups were inactive because of a lack of leadership, organisation, collaboration, planning and financing (IRIM 2019). By 2024, the UCC had established 20 community-based organisations (CBOs) with membership ranging from 16 to 83 households (Yanjinpagma 2024). Each CBO is led by an elected leader and supported by two community rangers and a community-banking unit. The CBOs have defined territorial boundaries and signed management contracts with the District Authority, securing herders' tenure rights while clarifying their conservation responsibilities. Motivated by the successful management of the LPA, the District authority expanded the initial LPA area from 137,018 hectares to 242,887 ha in 2024, providing additional habitat for endangered species like the musk deer and increasing UCC membership to 592 herders. The UCC develops an annual management plan that incorporates individual CBO plans, which are discussed and reported at bi-annual UCC meetings. Each CBO also holds monthly community-banking meetings to facilitate loan disbursement and repayment among members and to discuss ongoing activities.

UCC member herders' access to information and participation increased. In 2018, only nine out of 28 FUG members reported participating in conservation initiatives, primarily focused on forest cleaning. By 2024, participation has significantly increased. The UCC, in partnership with organisations such as the Arkhangai ETD, the Ecological Police, the Zoological Society Luujin and the District Government Office, has provided herders with briefings and training on local biodiversity, rangeland management, forest management, biodiversity monitoring and SMART (Spatial Monitoring And Reporting Tool) patrolling. According to the endline report, 72% of survey respondents participated in various training sessions, attending an average of seven meetings over the past three years. In addition, 61% engaged in planning and conservation actions, on an average of four times during the same period, and 42% of respondents were involved in monitoring activities, averaging four instances over three years. These learning opportunities have led to a positive shift in attitudes among herders, transforming them from poachers and illegal loggers into protectors of the LPA.

UCC members engaged in collective conservation actions. Thanks to a positive change in attitudes, UCC herders are now proactively involved in various conservation activities, including waste clean-up, forest thinning, fencing to protect young trees from grazing, safeguarding springs and conducting SMART patrols. These collective efforts have contributed to improved ecological outcomes. In 2018, surveys indicated prevalent illegal logging, cedar nut collection and marmot poaching, often without detection by law enforcement. Records from the Arkhangai ETD in 2024 revealed zero instances of poaching or illegal logging, with herders reporting no knowledge of such activities in their areas.

LPA women: housekeepers of CBO affairs. Women play a vital role in conservation and community-banking activities, particularly regarding organisational and logistical tasks. They have equal rights to run for leadership positions within CBOs and community banks and to access learning and development opportunities offered to UCC members. In addition to their essential herding and household responsibilities, women ensure high attendance at CBO meetings, prepare meals and appropriate clothing for annual activities such as forest cleaning and tree planting, and manage household chores, which allows men to engage in conservation efforts. Women lead about 10% of CBOs and 60% of community-banking groups; 90% of community banks have female secretaries and 50% have female accountants. Although more physically demanding tasks, such as forest cleaning, SMART patrolling and waste management, are predominantly undertaken by men, women are indispensable in governance-related functions, including financial management, meeting documentation, CBO planning, monitoring and dairy marketing.

Ecological outcomes

The UCC initiatives have led to significant ecological outcomes within the KMGT LPA, demonstrating improvements in forest health, wildlife populations and rangeland management.

Forests. The KMGT LPA is predominantly covered by conifer forests, encompassing 78,631 ha or one third of the LPA. These forests provide critical habitats for endangered species and a diverse range of rare plants, herbs and berries. Compared to the 2018 baseline, forest conditions have significantly improved, with reduced logging and notable regeneration observed (Marshall-Stochmal et al. 2020). The UCC has implemented an annual forest-cleaning event, a signature initiative in Arkhangai, focusing on clearing 63 ha and rehabilitating 8 ha of forest. These efforts help eliminate debris, promote new growth, prevent wildfires and provide herders with additional income while supplying towns with affordable firewood. Additionally, constructing fences around young trees has effectively supported natural regeneration by preventing damage from livestock. These events serve as collective missions for UCC members, fostering team spirit and enhancing their contributions to community wellbeing while strengthening social capital. In 2023, the initiative engaged 70 members from nine forest CBOs and five partner organisations to clean a 10-h area, resulting in the harvesting of 960 cubic meters of firewood, benefiting 240 households with discounted prices, generating over US$14 thousand in income for participating herders.

Wildlife. The KMGT LPA is home to several globally threatened species, including the Mongolian marmot (*Marmota sibirica*), Siberian musk deer (*Moschus moschiferus*), snow leopard (*Panthera uncia*), Siberian ibex (*Capra sibirica*) and white-throated bush chat (*Saxicola insignis*). Notable bird species such as the Saker falcon (*Falco cherrug*) and Steppe eagle (*Aquila nipalensis*) also inhabit the area. The UCC's annual monitoring of musk deer, marmots and birds has indicated an increase in marmot populations, stable musk deer numbers and consistent bird survival, alongside herders reporting increased sightings of deer and marmots. Key factors contributing to these positive outcomes include the implementation of institutionalised conservation measures, such as regular SMART patrols by community rangers and annual joint patrols conducted with Arkhangai law-enforcement agencies and UCC rangers, which help prevent and detect poaching and illegal logging. The positive changes in herders' attitudes and increased public awareness within the UCC and neighbouring communities have further supported these conservation efforts.

Rangelands. The KMGT LPA's mountain forest-steppe ecosystem is home to 191 plant species, predominantly perennial herbaceous plants (87%), including 52 medicinal plant species and 22 that require protection. Notably, this includes one endangered species (*Gentiana macrophylla* Pall.), ten rare plant species, one endemic species (*Astragalus galactites* Pall.) and ten species classified as intermediate endemics.

However, the ecosystem faces significant challenges because of a doubling of livestock numbers over the past decade, such that carrying capacity is exceeded by 6–30 times in summer-autumn pastures and 2–5 times in winter-spring pastures across the LPA (Ariunsuren 2012). To address these issues, the UCC has organised various management training sessions and supported livelihood diversification activities aimed at reducing reliance on livestock products, such as tourism, forage planting and forest cleaning. While engaging private livestock holders has proven challenging, livestock numbers have decreased by 15.6%, with a notable decline in number of goats compared to 2018.

Discussion

This study illustrates the transformative impact of the UCC on the KMGT LPA. The findings indicate that improved organisation and community engagement empower herders to become environmental stewards, aligning with existing literature on the efficacy of local institutions in conservation efforts (Berkes 2007, Ostrom 1990). Significantly, the role of herder women emerges as essential in both conservation and pastoralism; their contributions, ranging from managing community activities to facilitating knowledge sharing, underscore the importance of empowering women in pastoralist societies for enhanced environmental stewardship and resource management. While UCC initiatives have led to improvements in forest health and wildlife populations, persistent rangeland degradation because of overpopulation of private livestock poses ongoing challenges. This highlights the necessity for continued efforts to address economic pressures contributing to overgrazing. Increased demand for underutilised livestock products (skin, hides, wool and hair) could incentivise herders to reduce their herd sizes. Currently, herders mainly sell cashmere, camel wool and meat, while byproducts are often discarded or low-priced. If demand for these additional products were boosted, herders could earn more from each animal, potentially reducing livestock numbers and alleviating overgrazing pressure. However, for this to succeed, stricter rangeland management regulations would be vital.

In conclusion, this study demonstrates the potential for CBC initiatives to bring about positive change while emphasising the need for adaptive strategies that consider socio-economic dynamics. Fostering resilience within pastoral communities is crucial for preserving the vital ecosystems they depend upon.

Acknowledgements

We express our gratitude to the ZSL for funding support, which enabled completion of both baseline and endline assessments for evaluating the social and ecological outcomes of the KMGT LPA.

Traversing transdisciplinary terrain: a journey from knowledge integration to decolonial awareness

Fernández-Giménez, ME[1]; Bubar, R[2]; Souza, C[2]

[1]Dept. of Forest & Rangeland Stewardship, Colorado State University; [2]Dept. of Race, Gender and Ethnic Studies, Colorado State University

Key words: traditional knowledge; Indigenous methodologies; feminist research; participatory research; collaborative autoethnography

Abstract

Rangelands and the people who live and work in them confront growing complex and "wicked" challenges in the face of interacting environmental, demographic, socio-cultural, economic and political changes. To address these challenges, rangeland scientists increasingly turn to transdisciplinary research approaches—those that span multiple disciplines and engage diverse social actors in the research process—to co-produce actionable knowledge for living with complexity and managing wicked problems. We use a collaborative auto-ethnographic approach to tell stories of our 30-year journey of studying, collaborating and co-producing knowledge with pastoralists and ranchers across three continents. As we reflect on our learnings through the lenses of feminist, decolonial, and Indigenous research theories, methodologies, knowledges, and ethics, we ask how these approaches can be meaningfully applied to pastoral and ranching systems. We celebrate the inherent strengths of rangeland research as an applied and place-based science. Yet, both the literature and our experiences reveal limitations in current applications of transdisciplinary knowledge co-production, largely attributable to inequitable power relations and inadequate ethical frameworks. Such limitations appear rooted in the colonial and productivist paradigms and practices that continue to dominate mainstream academic and research institutions. To achieve more effective and enduring rangeland outcomes, mainstream institutions could transform in ways that enable rather than constrain boundary-spanning research partnerships that center genuine (not transactional) reciprocal relationships with pastoralist communities and Tribal Nations. We envision a future where such partnerships take root in ethical frameworks that respect pastoralists' rights and knowledge sovereignty, consider multi-generational implications of research practices and outcomes, and call for care-full research guided by a critical decolonial approach that considers Indigenous and community concepts of relevance, time, reciprocity, respect, appropriate communication and power relations.

Introduction

Over the past 30 years, rangeland science and management have increasingly recognized the wisdom of traditional pastoralist practices embedded in Indigenous and local knowledge systems (Sharifian *et al.* 2023). Always an inherently interdisciplinary field, rangeland science has also progressively turned to transdisciplinary research approaches that integrate social, ecological and physical sciences and bring together knowledge holders from varied sectors of society to co-produce knowledge for managing the wicked problems that rangeland and pastoral systems increasingly face (Tengö *et al.* 2014; Knapp *et al.* 2019; Reid *et al.* 2021). These diverse and intertwined streams of learning grow out of diverse theories and methodologies, including feminist (Haraway 1988; Harding 1991), Black feminist (Hill Collins 1986; hooks 2000; Hill Collins and Bilge

2016) and Indigenous and decolonial feminist (Lugones 2010; Kovach 2021) ones, and from our lived experiences as researchers and community members. In this keynote paper, we collectively reflect on the trajectory of transdisciplinary research approaches in rangeland science as represented in the lived experiences and publications of one rangeland social-ecological scientist (MFG). We use this series of collaborative autoethnographic vignettes to highlight successful strategies for combining knowledges from different disciplines, communities and sectors of society in ways that benefit rangeland peoples and landscapes, and to learn from past missteps. Feminist theories help us to consider the ways colonial scientific institutions condition transdisciplinary research approaches and Indigenous methodologies, and offer inspiration for institutional transformation toward a more equitable and relational transdisciplinarity. As Kovach (2021, p. 12) notes, "Indigenous methodologies are well positioned to unpack and unsettle the [Western] research-policy-practice cycle influencing Indigenous life."

Methods

We use collaborative autoethnography (Ellis *et al.* 2010; Lapadat 2017) to describe MFG's lived experiences of traditional knowledge, participatory, and transdisciplinary research and to analyse how they relate to wider cultural and social contexts of these experiences, including the settler colonial culture of US academia and rangeland science specifically, and the Tribal Nations, Indigenous and pastoralist cultures where her research often takes place. The three co-authors first co-developed a process for making meaning from MFG's research experiences, and identified key issues to focus on within and across project narratives: ah-ha moments, Indigenous and feminist insights, structural components, cultural and language barriers, lessons for transdisciplinarity, and visions for the future. Drawing from research memos, published accounts of the projects, and memory, MFG drafted vignettes of six projects spanning her 35-year research career and wrote short reflections on each. RB and CS asked further questions, guided MFG to consider the larger structural forces at work, and wrote responses to MFG's reflections, further contextualizing her experiences and framing them from Indigenous and feminist perspectives. MFG revised each vignette to integrate the most salient learnings, incorporating RB and CS's insights.

In keeping with qualitative and feminist methodologies, we briefly note our positionalities. MFG is a multi-ethnic (predominantly Spanish and Anglo-American), interdisciplinary rangeland scientist from a socio-economically and educationally privileged background, recently retired from her position as Full Professor. RB is a Native and Irish American scholar and a first generation Full Professor. She has worked with Native American organizations and Tribal Nations throughout the U.S. on child maltreatment and her recent work considers the impact and resistance of Native peoples living within a settler colonial state. CS is an AfroLatinx (Puerto Rican and Cape Verdean) first generation Associate Professor whose interdisciplinary work focuses on qualitative inquiry (critical ethnography, testimonio as method and methodology) and Decolonial and Intersectional Feminist theory.

Collaborative Autoethnographic Vignettes

Traditional Ecological Knowledge of Mongolian Pastoralists (TEK): My initial work in Mongolia involves ecological fieldwork and traditional ethnographic research, living alongside herders for months at a time. I want to understand how the major changes in Mongolia's political system and economy would affect herders' lives, livelihoods and land use practices, and how these in turn will impact the rangeland conditions. I am also very interested in the role herders' ecological knowledge plays in their decision-making. I have formal training in both ecology and anthropology. Through months of living with, interviewing and observing herders I come to understand that herders' ecological knowledge is reflected in their everyday practices and norms of pasture use. I find that my observations on pasture management do not fit with the neat conceptual categories in the existing theory about commons governance. Eventually, I realize I need to pay attention to what is, not what theory says should be, and use my observations to revise theory. As I reflect back, I see that the TEK aspect of my work was extractive, shaped by my training in siloed academic disciplines. I lacked a model of participatory research and training in research ethics. I did not co-design the research with herders and it had not clear and immediate benefits for them. I authored articles from my work alone or with my dissertation advisor. Yet I did learn that traditional knowledge is more than biophysical facts and observations, and that it encompasses ways of doing and thinking, skills and technologies, cultural norms and values, and social relationships like reciprocity. The significance of reciprocity in Mongolian culture became a through-line of my decades of work there, both in terms of its importance to understanding social-ecological dynamics, living relationality and in how it influenced my relationships and work with Mongolian individuals and institutions. Thirty years on, all my subsequent work has been co-authored with Mongolian researchers and much has been co-designed by with herders and products co-developed with and for communities. I have mentored many Mongolian students including three who earned PhDs at my university.

Participatory Rangeland Planning and Curriculum Development with the Tohono O'odham Nation (TON): The Tohono O'odham Nation spans the US border with Mexico and encompasses over 2 million acres of desert grasslands and Sonoran desert ecosystems. O'odham people incorporated livestock into their culture and economy during the Mission period, and cattle continue to play important roles in O'odham society today. In the early 2000s, the Tohono O'odham Nation is taking over management of its natural resources from the US Bureau of Indian Affairs (BIA) under the provisions of the Indian Self-Determination Act (PL 93-638). Unlike in Mongolia, in this case, the Tribe invites me to advise on grazing and rangeland management, and specifically the development of a Tribal grazing code. Our relationship starts with my participation in monthly meetings with the newly formed TO Natural Resources Department, and mostly listening. Two projects eventually grow from this, a pilot participatory rangeland planning project and later, a participatory curriculum development project. After six months, I suggest the idea of a pilot participatory community-based rangeland management project. Past efforts to impose top-down grazing regulations have met with resistance. Maybe working at the community-level with a single grazing district and helping the community come up with its own set of rules could lead to a more bottom-up process that communities would support. After Tribal Council approval, and with guidance and support from a key community member, the Sif Oidak district agrees to take part in this pilot. Masters student John Hays, formerly a working cowboy, serves as a critical link to the community. John participates in 19 round-ups in Sif Oidak over a year, building trust and demonstrating reciprocity by helping with a dangerous and labor-intensive task. He also helps each of Sif Oidak's 9 villages identify and map areas of resource concern and opportunities for restoration. We then help them apply for federal funds to implement restoration. The resulting resource management plan looks different from what we envisioned. It focuses on education and cooperation among villages instead of rules and by-laws (Hays and Fernandez-Gimenez 2005). We learn that support for cooperation and reciprocity is more important than attempting to solve issues through formal rules and sanctions that further fray inter-community relationships (Fernandez-Gimenez *et al.* 2008).

The community's interest in education leads us to apply for another grant in partnership with the TO Resource Conservation District, to develop a rangeland curriculum specific to the Tohono O'odham lands and culture. Another Masters student, Jennifer Arnold, leads the implementation and evaluation. A curriculum advisory committee composed mostly of O'odham cultural experts, ranchers and natural resource professionals guides the project. Thirty-nine individuals participate in the committee over a two-year period, and a core group of seven members are deeply engaged in all phases of the research, including developing the research goals and methods, interpreting the findings, and authoring publications. Instead of a TEK documentation approach, the curriculum committee incorporates O'odham traditional knowledge, values and priorities directly, by shaping the curriculum and participating in the delivery of the workshops. O'odham participants choose what they want to learn and from whom, including a mix of both local O'odham elders and experts and outside non-O'odham presenters, with nearly two thirds of the presentations given in O'odham. The workshop series begins with elders' stories of water and ends with an O'odham presentation about drought, the desert and the monsoon rains (Arnold *et al.* 2007). The advisory committee identifies a goal to "incorporate values of cooperation and community" and their importance for rangeland management into the curriculum. The importance of cooperation emerges in various ways, leading us as academic researchers to draw on the concept of social capital as an analytical lens. One O'odham elder objects to the use of non-O'odham theories to explain O'odham ways, and this leads to an extensive discussion about the project's goals and the role of research on the TON. Ultimately, we use a social capital framework and a core group of O'odham participants help refine the analysis and interpretations, which are supported by political leaders, elders and other community members (Arnold *et al.* 2007). As I reflect on this dynamic today, I wonder if we could have co-created an O'odham theoretical framework based on the importance of relationality instead of imposing a social capital framework (Kovach 2021).

Mongolian Rangelands and Resilience (MOR2) (Fernandez-Gimenez *et al.* 2019a): Back in Mongolia, it's now 2008, a decade and a half after my original work there in the early 1990s. Rangelands and herders are suffering from increasingly frequent droughts and severe winter storms, exacerbated by declining pasture conditions. To address declining livelihoods and rangeland health, herders, with support from international development organizations, have begun to organize into local community-based rangeland management (CBRM) groups to manage their rangelands, yet there is little communication or coordination among these efforts. Project leaders see the value in learning from diverse project experiences, and with their support we begin to design a research effort. Rangeland social-ecological changes in Mongolia are a wicked problem—one with high complexity, no simple solutions and multiple drivers within and across scales. We need a multi-disciplinary team of researchers with expertise in rangeland ecology, climate change, hydrology, human ecology, geography, policy and sociology. To design a relevant study that asks the right questions to produce information that is credible and usable, representatives from herder communities, conservation and development organizations and government must participate in shaping the questions and design. We bring together researchers from the US and Mongolia with diverse expertise and organize a two week research planning process in Mongolia that begins with a week-long field trip to build trust among members of the newly formed international team, and ground our science in on-the-ground realities. The second week we host a 5-day interactive workshop in the capital of Ulaanbaatar, where scientists, conservation and development practitioners, herders and government officials collectively identify and prioritize key issues affecting Mongolia's rangelands and herders, draw connections among these complex factors, and finally, agree on a primary issue and research question and outline an overall research design.

It takes several years to secure funding to implement our ambitious research plan across 36 districts (*soum*) in Mongolia's 4 major ecological zones. The quasi-experimental design compares the process and outcomes of community-based rangeland management (CBRM) in adjacent districts with and without formally organized CBRM groups. Almost half of our core team are Mongolians, including two PhD students and two post-docs. Each subteam is co-led by Mongolian and US scientists. We train over 50 young Mongolian researchers and students who participate in field teams alongside senior Mongolian and US researchers. We collaborate with other organizations to make the trainings in research design, social and ecological data collection, quantitative and qualitative data analysis, and scientific writing available to students and professionals beyond those on the MOR2 team. We hold annual all-members team meetings in Mongolia to discuss our progress and findings, and plan for the next phases. Our core team includes a social scientist who interviews or surveys each member annually and facilitates an annual reflective retreat that helps us identify and redress power imbalances and communication issues on the team, strengthening trust and mutual accountability and reciprocity. Later, we hold monthly informal day-long analysis and writing retreats that help break down disciplinary barriers and reduce power imbalances between graduate students and faculty.

Consistent with principles of reciprocity and data sovereignty, the expanded project team agrees that all team members will have access to the data collected by the project, and that it will be permanently archived and available for use by Mongolians and other scientists who request it. We develop formal guidelines for data use and authorship. To give Mongolian researchers the experience of peer review and opportunity to present their findings to an international audience, in the final year of the project we organize a major international conference in Ulaanbaatar. All the project participants have a chance to attend, present and publish a peer-reviewed paper in the fully bi-lingual conference proceedings

Following through with reciprocity to 36 different herder communities spread across Mongolia proves challenging. We develop community-specific brief written summaries of interim findings and deliver them in brochure form back to some but not all of the communities. One of the Mongolian post-docs works with one community to develop a book by and for community members. Finally, we organize four regional workshops for herders and local government representatives from each study community where we share findings, facilitate interactive discussions to "ground-truth" our scientific results with local knowledge, and engage participants in scenario-planning to consider what our findings might mean for their communities' futures.

Ten years after the project's end, the impacts of MOR2 persist. Many of the young Mongolian researchers who took part in our project and trainings went on the earn graduate degrees at top universities and today contribute their skills within Mongolia to teaching, research, entrepreneurship, and direct action with herder communities. MOR2 was a transformative experience for many of us. The team exemplified respect, responsibility, reflexivity and reciprocity among members. At the same time, the very aspects of it that made it powerful scientifically—the large sample size, quasi-experimental design and broad spatial extent—also made it impossible to develop meaningful long-term and truly reciprocal relationships with all of the participating communities. The funding source and institutional expectations also influenced the power dynamics such that Western science dominated our decision-making and outputs.

Collaborative Adaptive Rangeland Management (CARM) (adapted from Wilmer)***:*** On eastern Colorado's Great Plains, rangelands and ranchers face multiple environmental, social, economic and policy challenges from climate change to land-use change to demographic change and shifting public values related to rangeland ecosystems and animal agriculture. This broad expanse of shortgrass steppe from the foothills of the Rocky Mountains to the mixed grass prairies of Kansas and Nebraska are the traditional homelands of the Ute, Cheyenne and Arapaho Tribes, who were violently expelled during the process of Euro-American colonization and settlement in the 19th century. In the early 20th century, settlers attempted to plow and farm the area, with disastrous consequences, leading to the Dust Bowl, and subsequent creation of the National Grassland system and the US Department of Agriculture's Central Plains Experimental Range (CPER). Over 80 years, CPER generated a strong body of rangeland science, yet the conventional research approach had limitations. It excluded complex social dynamics and public participation and focused mainly on production problems, ignoring wildlife, conservation and social problems.

By the 2010s, challenges to ranch sustainability and conservation have intensified and CPER researchers recognize they need to work in a different way. They ask me to join their team as a social scientist. The team is dominated by ecologists, but also includes me and Hailey Wilmer, as social scientists. Later, a hydrologist and an economist join us. The research team invites a diverse group of stakeholders including representatives from federal and state natural resource agencies, conservation organizations and ranchers from the local grazing association, to participate as co-researchers. The project team designs and implements a comprehensive collaborative adaptive rangeland management (CARM) project with the stakeholder-defined goals of enhancing ranch profitability and drought resilience, bird and plant biodiversity, and social learning. The team divides the experiment station into two, ecologically paired ranches, and manages one with the "business as usual" season-long grazing approach common in the area, and on the other gives decision-making control to the stakeholder group, keeping the stocking rates the same on both halves. Scientists monitor and evaluate outcomes on both ranches, incorporating stakeholder-devised indicators as well as conventional rangeland and wildlife monitoring metrics. The stakeholder group and research team cycle through goal setting, stocking, grazing, prescribed fire and drought decisions, tracking learning as we go. The group commits to this ranch-scale experiment for 10 years. Plenty of time to learn and adapt.

The decade that followed is incredible, and incredibly challenging. Working and learning together in this context is entirely new for both researchers and stakeholders. From the first goal-setting workshop, we realize we face an uphill journey to understand each other's disciplines, goals, and communication styles. Researchers and stakeholders from different backgrounds find we come from entirely different social worlds, with different ways of knowing and learning. Trust – in people and in data – is not a given. Additionally, while everyone agrees on the overarching goals, the stakeholder-managed steers gain less weight than those managed conventionally, efforts to improve bird populations and plant diversity are inconclusive, and ranchers initially reject data that suggested prescribed fires could benefit rangelands, and vote against the use of fire. To top it all off, the roles of researchers as scientists, facilitators and decision-makers become confused. As researchers, aren't we stakeholders, too? How are we influencing the stakeholder group's decisions? Somehow, through a mix of courage, stubbornness and social cohesion that forms out of time together on the land and flexible, supportive leadership, the CARM process begins to work. Trust begins to develop as all the participants—stakeholders and researchers—learn about each other's social worlds and ways of knowing through informal interactions like a tour of one stakeholder's ranch. They become vulnerable, they listen, and try to understand one another's point of view.

Throughout the project we try to create more opportunities for these informal interactions, and empathy, curiosity and compassion start to build the key ingredient to CARM, trust. Trust supports a culture of flexibility and creativity, experimentation and learning, which in turn leads to scientific productivity and adaptive capacity. Because social science is integrated into the core of the project, we are able to document how the project facilitates social learning, and to reflect honestly on the challenges and opportunities of the approach. Some of the key ingredients to learning and enduring collaboration are: flexible, inclusive problem definition; respect for context and history; effective team leadership and power sharing; long-term investment in relationships and a long time horizon for the project; capacity for collaborative creativity; sufficient resource allocation; and a study design that invited diverse research methods and questions (Wilmer *et al.* 2018; Wilmer *et al.* 2022). CARM has inspired similar approaches in Nebraska and in Idaho, where Hailey Wilmer leads the Rangeland Collaboratory, focused on building relationships among diverse stakeholders and researchers to help ranchers, land managers and conservation organizations manage iconic landscapes for multiple species and values. Despite these successes, I now recognize that we failed to invite key rightsholders, Tribal representatives, to participate in CARM. I wonder how different might the process have been with their participation, and why we omitted them.

Co-Creating Knowledge for Action with Women Pastoralists in Spain (CCK): Extensive livestock management has shaped Spain's landscapes and cultures for 7000 years, but the 20th century saw major structural changes in agriculture that have led to industrialization of animal agriculture, rural depopulation, and transformation of these socially valued landscapes, the ecosystem services they provide and human communities that inhabit them. The number of women-led livestock operations is increasing, yet women pastoralists remain largely invisible in the public eye and absent from decision-making spaces. Inspired by work with women ranchers in the southwestern US (Wilmer and Fernández-Giménez 2016), and my recognition that my own research in Spain and Mongolia have largely overlooked the knowledge and experiences particular to women, I decide to mend this gap. On reflection my blinders here were due in part to disciplinary assumptions in rangeland science and in part to the culture of pastoralism in Spain, where I was told by many experts not to bother interviewing women because they are not directly involved in land and livestock management. This turns out not to be true.

Two colleagues, Elisa Oteros-Rozas and Federica Ravera, and I partner with networks of women pastoralists in Spain (Ganaderas en Red and Ramaderas.cat) to research the lived experiences of Spanish women pastoralists. We take a feminist research approach. For us, this means a rejection of simple binaries and universalizing claims about women's lives. Instead, we are interested in the diversity of women's experiences and how their multiple social locations interact to shape their power and access to pastoral resources and decision-making. We draw on our outsider within perspectives—as women in the male dominated field of rangeland science, and working with women herders in a culture where herding is understood to be a man's job. As feminist researchers, we value multiple ways of knowing and our research has emancipatory as well as scientific goals. We center care in interactions with research participants and co-researchers, and commit to reflexive practice where we regularly examine our process and power relations with one another and our research participants (Ravera et al. 2021).

In contrast to the MOR2 and CARM projects, we have no big funding sources to support the work, but also less pressure to meet funders' expectations regarding research publications. Building on Elisa and Federica's existing relationships with GER and ramaderas.cat, we gain support for the project and women in both networks agree to participate. We visit and interview women in southern, northern and eastern Spain on their farms, frequently in remote areas. We analyse the transcripts together, returning their transcript to each participant. We organize participatory workshops in each region where we share meals made from the women's products, interpret and refine interview themes, and facilitate discussions of women's priorities for action. During covid, we organize several follow-up virtual workshops with broader audiences. We send copies of our final report in Spanish to all participants and make it freely available on the web. One participant writes a companion essay to a book chapter we write about women pastoralists and climate change. Members of the GER network present at the Society for Range Management, are active in the IYRP, and help women in other countries to establish their own networks.

CCC Workshop: My continuing dis-ease about my positionality as a non-Indigenous researcher and the ways in which, despite a commitment to participatory research, my projects continued to privilege conventional Western scientific outputs over Indigenous science and lasting community benefits, motivate me to work with Center for Collaborative Conservation (CCC) director Robin Reid to organize a workshop on decolonizing collaborative conservation. We also recognize the wealth of knowledge, experience and adaptive capacity held by Indigenous communities and land stewards despite centuries of genocide, displacement and dispossession. We think we were ready to engage in decolonization of collaborative conservation. As we assemble a diverse organizing committee, bring in Indigenous facilitators to work with us, and invite Indigenous people from around the world to participate, we are forced to re-examine our readiness and to recognize that we didn't understand what decolonization means from an Indigenous perspective. Through the workshop, we begin to learn from Indigenous people what a decolonial perspective on collaborative conservation might look like.

The tone and content of the workshop changes immediately once an Indigenous facilitator joins the team, and Indigenous participants report feeling seen and validated based on the process and content of the workshop. The workshop spurs enthusiasm and willingness of the CCC and others at CSU to support and validate Indigenous researchers at CSU and elsewhere. I experience several ah-ha moments during the workshop. First, during the workshop, I am struck by the ongoing harms that Indigenous students experience within colonial education systems that devalue traditional knowledge and erase Indigenous communities and realize that my own work perpetuates the system that causes these harms. Second, I gain appreciation for the importance of history and the value of theory to understanding how and why Indigenous communities have been dispossessed and displaced, and their relationship to their land. Learning this history and theory is essential to being an effective non-Indigenous collaborator and ally. I learn that decolonization is not a metaphor (Tuck and Yang 2012); to decolonize conservation we need to work at practical and policy levels to return land, water and management authority to the original stewards and prioritize Indigenous life ways. Third, I learn the transformative power of holding space for people with marginalized identities to share experiences and support each other across genders and generations. Participants share solutions grounded in healing within Indigenous communities, restoring relationships to land, and developing equitable collaborative partnerships with external allies, governments and research institutions. The workshop leaves me more committed to and hopeful for the possibility of change, and with a deeper understanding of how to collaborate effectively with Indigenous communities.

Discussion, Conclusion and Implications

Feminist philosophers advance the idea that all knowledge is embedded in particular social, cultural, historical and political contexts, and reflects the lived experiences of those who produce it (Haraway 1988; Harding 1991). Decolonial feminist theory embraces the multiplicity of knowledges and experiences and values them equally (Tuhiwai Smith 1999; Kovach 2021). Indigenous methodologies are research by, for and of Indigenous researchers (Tuhiwai Smith 1999), including Indigenous epistemologies, theories, methodologies and methods (Tuhiwai Smith 1999; Kovach 2021).

As transdisciplinary approaches are mainstreamed within rangeland science and management, feminist, decolonial and Indigenous thought can inform and improve our approaches. In the vignettes above, we describe the lived experiences of MFG as a multi-ethnic woman and interdisciplinary researcher working in ecological and social sciences, whose positionality led her to become a boundary-spanner in multiple ways. Reflecting on her experiences through decolonial and feminist lenses underscores how institutional culture and structures in academia, steeped in colonial scientific ways of thinking and doing, promoted extractive research practices and created barriers to investing necessary time, resources and heart into building equitable and reciprocal relationships with pastoralist and ranching communities and Tribal Nations. Some of the ways this occurred are obvious in hindsight, such as insufficient graduate training in research ethics, an academic culture that rewards above all else research productivity measured in number of articles, impact factors, and the size and prestige of research grants, and the lack of models and resources for developing genuinely equitable and reciprocal participatory research relationships. Academic culture influences research practices in more subtle ways related to MFG's specific positionality as an interdisciplinary and multiethnic woman researcher. For example, as a junior scholar, more senior faculty discouraged her interdisciplinary aspirations, dismissed traditional Indigenous knowledge as a valid research interest, and questioned her qualifications and abilities, leading her to question herself and to double-down in her efforts to meet and exceed the academy's expectations for productivity. The primacy of Western science remains deeply engrained and internalized, as illustrated in the power relations that played out in the Mongolian TEK, TON and MOR2 vignettes. Twenty years on from the TON project, MFG now has examples of Indigenous theory-building that might have led us to a different approach (Kovach 2021). Thinking about the final vignettes presented here—Co-creating Knowledge for Action with Women Pastoralists in Spain and our workshop on Collaborative Conservation through a Decolonial Lens—we consider how they *felt* different—in the heart and in the body. This different affect, we reflect, results from a different approach—one that prioritizes *care* and *doing things in the right way*--and a different underlying ethic—an *ethic of generosity* that flows from a *philosophy of abundance* and incorporates Indigenous research ethics. This approach stands in contrast to the dynamic of competition in academia, based on a worldview grounded in scarcity.

The challenges outlined above are not unique to these specific vignettes, and are echoed in much of the recent literature on transdisciplinarity (Knapp *et al.* 2019; Reid *et al.* 2021) and knowledge co-production (David-Chavez and Gavin 2018; Chambers *et al.* 2021; Chambers *et al.* 2022). Yet despite the structural and cultural challenges and resulting missteps, the vignettes also highlight examples of positive outcomes, successful transdisciplinary research and constructive mutually beneficial research relationships with rangeland stewards and communities. The practices that supported these outcomes are highly aligned with principles of feminist (Haraway 1988; Harding 1991) and Indigenous research (Kirkness and Barnhardt 1991; Kovach 2021; Montgomery and Blanchard 2021; Tsosie *et al.* 2022; David-Chavez *et al.* 2024). Indigenous research, when it employs Indigenous methodologies, including Indigenous epistemologies and theories, is specific to particular Tribes and cultures, and at times may not be appropriate for all researchers. However, the practices associated with Indigenous and feminist methodologies can apply in a wide range of transdisciplinary and participatory research contexts.

1) "The process is the product" and the importance of *doing things in a good way*. Pragmatically, MFG navigated the productivity demands of academic culture by focusing research on the process of transdisciplinary collaboration. In most of the vignettes above a significant part of the learning came from building in a component of studying the collaborative process, which enabled us to publish widely about the processes of transdisciplinary and participatory research. In CARM, MOR2 and CCK, the learning resulted from a deliberate practive of *reflexivity*, the process of collective critical reflection on power relations in the research process (Ravera *et al.* 2023). An important aspect of Indigenous research and working with Indigenous peoples, RB emphasized the importance of doing things in a good way. In Indigenous research, this includes preparation of the research and the researcher, recognizing and following ethical and cultural protocols, connecting with community, reciprocity (sharing knowledge and food, giving back to the community) and respectfulness (Kovach 2021).

2) *Relationships* form the core of successful transdiscipilanary research. Ideally, relationships develop before research begins (Kovach 2021; David-Chavez *et al.* 2024) and outsider researchers come at the invitation of the community (TON). It takes time to establish trust, which often grows through informal interactions (e.g. shared meals, field trips as in CARM, CCK) and shared experiences like the researcher taking part in and contributing to community life and work (MON TEK, TON). Trust develops through mutual vulnerability—where individuals reveal feelings or ideas that put them at risk. Trust also depends upon respect,

honesty, and integrity. Researchers and community members must follow through with what they say they will do and not promise what they cannot deliver. From an Indigenous perspective, relationships include not only those with people involved in any aspect of the research process, but also understanding and respecting the wider web of relationships and kinship with ancestors, and other living and non-living more-than-human beings (Kovach 2021; Tsosie *et al.* 2022). Relationality thus extends beyond the human relationships to our interdependence with and responsibilities to all beings.

3) *Respect* is a foundation for relationship-building and includes respect for Tribal governance, cultures (Kirkness and Barnhardt 1991), individuals (Tsosie *et al.* 2022) and their social worlds (Fernandez-Gimenez *et al.* 2019b), and in an interdisciplinary context, for different epistemologies and methodologies associated with different disciplines (MOR2, CARM) (Fernandez-Gimenez *et al.* 2019a; Wilmer *et al.* 2022). For outsider researchers working in cultures different from their own, learning the language and cultural protocols is a sign of respect. Fluency in the language improves communication and reduces power differentials in research. Respect also encompasses respect for Indigenous communities' sovereignty, including their right to govern data generated from research (David-Chavez et al. 2024), and respecting methodological preferences and options that include participatory and Indigenous research methodologies. Along similar lines, Wilmer et al. (2021) suggest that respect for community and individual self-determination is a critical component of expanded ethical considerations for transdisciplinary research.

4) *Relevance* in an Indigenous research context includes the salience and appropriateness or research to the specific Indigenous community's experiences, perspectives, ways of knowing and doing, and priorities (Kirkness and Barnhardt 1991; Tsosie *et al.* 2022). In a broader transdisciplinary context, relevance relates the degree to which the research problem and approach are defined by relevant rightsholders and stakeholders (for example, as in TON, MOR2 and CARM), with outcomes that are likely to have a direct impact on managing "wicked" problems and improving community conditions.

5) *Representation* means that particular perspectives are present and included in the research process. For Indigenous communities, representation ensures that they share what is important and relevant to their community (Tsosie *et al.* 2022). Representation may be accomplished through advisory committees (TON) or direct participation by different rightsholders and stakeholders in research design and implementation (TON, CARM). MOR2 ensured that the research team included Mongolian researchers alongside US-based scientists in every discipline, and that the research problem, questions and methodology were co-developed and agreed upon by herders, conservation practitioners, government officials and researchers working together.

6) Responsibility includes honouring ethical and moral responsibilities both in in-person interactions and in with regards to data (David-Chavez *et al.* 2024), and accountability for people and knowledge put in the researcher's trust (Tsosie *et al.* 2022).

7) Reciprocity signifies giving back to a community or individual involved in the research process. It is a continual process of exchange essential to relationship-building and ensures that community members access benefits from the research (David-Chavez et al. 2024). As such, reciprocity can take many forms, but in transdisciplinary research, at minimum, it includes sharing data (e.g. transcripts), knowledge and learning with the community orally (e.g. workshops) and/or in written or other forms (e.g. film, photography) (TON, MOR2, CCK, CARM), or opportunities to co-author research articles or other products (TON, CARM). Other forms of reciprocity in a research context include organizing meals or social events for the community or research participants (CARM, CCK), helping the community with needed work (e.g. TON round-ups), or providing assistance during emergencies (e.g. during the 2023-2024 *dzud* MFG sent cash to Mongolian women in her study whose families were affected by the severe winter weather). We always offer a useful gift to research participants beyond the typical IRB incentive. True reciprocity is not transactional, but rather a demonstration of generosity in the context of an authentic relationship. From a practical standpoint, it is critical to include necessary resources in grant proposals to cover local hiring of community member experts and appropriate costs related to reciprocity (Kovach 2021).

8) *disRuption* represents the emancipatory aim of feminist research (Ulmer 2024). Transdisciplinary research aims to link knowledge with action to solve wicked problems, and participatory action research engages communities in analysing and addressing community-identified challenges. Feminist research contributes to these aims by disrupting patriarchal research institutions and processes, and by supporting research participants and community partners in fighting oppression and advancing their goals for social, economic or environmental change (CCK). CCK worked with existing networks of women pastoralists to support them in reflecting on their experiences of oppression and liberation, and in articulating goals for policy change. By doing research in a care-full way this project also disrupted established academic norms and

provided an example of an alternative research ethic. disRuption also occurs within an Indigenous intersectional lens when "An intersectional analysis becomes important to dismantle settler colonial logics to reveal moments of settler complicity" in classroom settings and also within Western research processes ((Bubar *et al.* 2022) p. 53), as occurred in the CCC workshop.
What kinds of institutions are needed to support research with Indigenous, pastoralist and other rangeland communities and Tribal Nations that is done in a good way, a way that respects these combined principles of Indigenous and feminist research? First, we clarify that, as Kovach (2021) notes, just as not all research with Indigenous Tribes and communities needs to use Indigenous methodologies, with pastoralist communities, a variety of different approaches may be appropriate, depending on the problem and questions. However, transdisciplinary research is often required to address the wicked problems facing pastoralist communities and rangeland systems. Some mainstream academic and research institutions are making incremental changes towards research that addresses some if not all of the 8 Rs above, for example through more and better training for junior scholars in inter- and trans-disciplinary and participatory research methodologies, including research ethics. Yet, the dominant competitive productivist academic culture persists; if anything the competition and pressures on faculty and graduate students grow steadily more intense. How can we work in a good way under these conditions? Kovach (2021) advocates that the academy develop appropriate criteria for evaluating Indigenous research, which would take into account not only peer-reviewed publications and grants, but other kinds of community-valued outputs and outcomes. While we (MFG) advise(s) young scholars committed to "engaged scholarship" to "make the process the product", publishing on participatory and transdisciplinary processes as well as the other types of learning from research captured in more traditional disciplinary publications, this strategy does not address other barriers to implementing research in a good way. We dream of academic and research institutions that invest in building relationships first—following the principles outlined above from Indigenous and feminist methodologies--where research priorities emerge organically from these relationships and the historical and environmental contexts and problems particular to these communities and places. Academics and researchers operate in a competitive environment, where we compete for funding, space, resources and recognition. These pressures to compete infect relationships between researchers and communities, often causing researchers to pressure communities in turn—this is especially true for non-Indigenous researchers who too often engage with Tribes and Indigenous communities in instrumental and transactional ways, rather than building relationships on a foundation of genuine respect, responsibility and reciprocity. This is the opposite of doing things in a good way, and it is driven in part by the productivist culture of mainstream academia, a culture rooted in an ethic of competition for scarce resources as opposed to an ethic of generosity and reciprocity arising from worldview of abundance. Our intent is not to homogenize, idealize or oversimplify diverse Indigenous ontologies or epistemologies. Nor is it to overlook the realities of many historically marginalized and disenfranchised communities. Rather, we ask for a radical rethinking of the ethical foundations for our work.

A year ago, at another rangeland conference, at the end of the Q&A in a concurrent session, a graduate student posed the question to the room—"but how do we engage with these communities?" referencing rural, often conservative, rangeland users in the Western US. I (MFG) responded, "Love is the answer." I did not mean this facetiously. I meant it genuinely, in the sense of Black feminist bell hooks (2000), who writes that love is an active choice and practice to nurture one's own or another's growth. Although saying this to such an audience made me vulnerabile, I did it to call in rather than call out our predominantly white and male field of rangeland ecology and management. Through the gaze of love we see each other's humanity, and that is a starting point. We may look at the world today and consider love is in short supply. War, genocide, dehumanizing treatment of humans by other humans, destruction of Earth. But this is a fallacy, a dangerous mistruth. Love is not a finite resource. Like the beauty of the grasslands, it is infinite. We direct care and generosity towards the objects of our love—including the self. I have had some degree of conventional academic success in my career, in no small part because the discrimination I faced motivated me to overcompensate in the research productivity department. This so-called success also threatened my physical and mental health and my family's well-being. Yet when I think of the most meaningful projects I have taken part in, and what gave them meaning, it has been the relationships with the research team and with our study communities, even more than the scientific insights, publications and broader impacts. Those relationships weren't just about making me, or other participants, feel good. In fact, a lot of the relationship building was difficult, even painful at times. It was the process of working through those difficulties and learning from them that made these projects work. The relationships, among individuals, communities and institutions were often the most consequential outcomes. At the most essential level, they were about love. Our shared love for rangeland landscapes, for the people that inhabit, steward and study them, and ultimately, for one another. That love is expressed through care, and through recognition, respect, commitment and trust (hooks 2000). Care for one another as individual human beings and communities, care for the rangelands and all their beings, and care for the research process. We do not look at the world through rose-colored glasses. This is hard work, but it is work worth doing. Moreover, because it is hard, this work is not worth doing in any other way than in a good way. We hope these stories from one researcher's life combined with insights from Indigenous and feminist methodologies provide both food for thought and actionable practices relevant to diverse rangeland and pastoral contexts.

Acknowledgements
We gratefully acknowledge Hailey Wilmer for helpful conversations and for providing a draft of the CARM vignette and reviewing a draft of this paper.

Key words: monitoring; remote sensing; land potential; state-and-transitions

Abstract

There is a growing thirst for data and digital tools to support adaptive rangeland management. Over the last two decades, adoption of standardized field monitoring methods has enabled unprecedented data collection across rangelands globally. Monitoring capability has been boosted by an explosion of remote sensing products and models that can leverage field datasets and cloud computing to extend predictions across space and time and produce new indicators of rangeland health. Integrating these datasets with decision-support tools has the potential to support the development of new knowledge systems and place data and interpretive tools in the hands of managers in the field. Here, we review examples of recent developments that are transforming how pastoralists, extensionists, scientists, and agencies make decisions about rangeland use and management. These developments leverage new perspectives on data quality, data harmonization and aggregation tools, models that produce new integrative indicators, standard frameworks for describing land potential, and applications of benchmarks to make objective and actionable decisions supporting adaptive land management. These improvements can dramatically simplify rangeland monitoring and assessment, in both developed and developing world contexts, in addition to increasing the decision-making value of rangeland monitoring.

Introduction

The world has now passed 1.5°C warming. As the climate continues to change, pastoralists and rangeland managers must adapt to novel growing conditions often exacerbated by interacting effects of invasive species, wildfire, drought, soil erosion and changing social and economic conditions. In this time of environmental change, monitoring the status, condition and trend of land health attributes is of critical importance for identifying threats, understanding risks, and anticipating change in rangeland ecosystem services and the sustainability of enterprises – and adaptively managing them. Monitoring land health indicators provides a means for pastoralists and other rangeland managers to objectively assess different attributes and the function of landscapes, whether they are changing, where, when and why changes are occurring, and evaluate the outcomes of management actions. Recent integration of large-scale monitoring datasets with digital tools for interpreting land health indicators offers new opportunities to develop approaches that provide pastoralists and other range managers with information and knowledge to simplify adaptive management decisions. Here, we review examples of big data and digital tools that are successfully transforming management decision-making on rangelands. We synthesize lessons learned from these developments that could support opportunities for new research, adaptive management approaches and international collaboration.

Standardize and upscale monitoring methods

Monitoring methods standardization has provided a foundation for using indicators to assess the status, condition and trend of ecological attributes that are important for understanding and adaptively managing rangelands. In the United States, the *Monitoring Manual for Grassland, Shrubland and Savannah Ecosystems* was developed collaboratively with rangeland scientists and managers to provide standardized methods for collecting data that can be used to describe soil and site stability, hydrologic function, the biotic integrity of landscapes, and derive other indicators of, for example, wildlife habitat suitability and biodiversity (Herrick et al. 2018). The standard methods include line-point intercept (LPI), which enables estimation of the fractional cover of vegetation by species and other ground cover elements, a vegetation height estimation method, the canopy gap intercept method which enables quantification of bare ground connectivity, and a method for conducting species inventory. Extensive training and observer calibration programs, supported by rigorous data quality assurance and quality control (QA&QC) approaches (McCord et al., 2021) and statistically valid sampling frameworks (Toevs et al., 2011; Stauffer et al. 2022), have enabled implementation of the standard monitoring methods by producers, land management agencies and research institutions at over 100,000 locations across privately and publicly owned and managed grazing lands in the United States since 2004. Similar standard methods have been developed and implemented elsewhere around the world, providing comparable opportunities for adaptive management informed by globally standardized land health indicators (Oliva et al. 2016; Tokmakoff et al. 2020; Dashbal et al. 2023). Recognizing the significant costs associated with implementing large-scale monitoring, the Land Potential Knowledge System (LandPKS) mobile applications (https://landpotential.org/ [Accessed 22 01 2025]) were developed to provide globally accessible and compatible field-based monitoring technologies (Herrick et al., 2017).

Harmonize monitoring data and models

A major challenge to the findability, accessibility, interoperability and reusability of large-scale monitoring datasets is that different monitoring programs tend to develop and use their own data collection tools and formats and data management systems. In the United States, the Database for Inventory, Monitoring and Assessment (DIMA) (Courtright and Van Zee 2011), Vegetation GIS Data System (VGS) and ESRI-based Survey123 apps, for example, are all used for data collection among users following Herrick et al. (2018). While data collection formats have been optimized to reduce errors in the field, they are not typically analysis friendly (McCord et al. 2023). Furthermore, databases and data management systems have tended to exist in isolation among user groups. Monitoring data may be collected and managed separately by different organizations and government entities, while cross-tenure management is not uncommon. Consequently, inference from indicator assessments has often been restricted to specific land use and tenure and the ability to make cross-scale assessments has been limited.

The Landscape Data Commons (https://landscapedatacommons.org [Accessed 15 01 2025]) uses modern cyberinfrastructure to harmonize and aggregate monitoring data, enabling unprecedented access to standardized monitoring data and calculated land health indicators (McCord et al., 2023). Open-source code and toolsets enable data harmonization and standardized indicator calculation (McCord et al. 2022), ingestion of raw monitoring data into staging and production databases, and data access through a web portal and application programming interface (API) – which are open to users globally. During data harmonization, a set of 58 common grazing land indicators are calculated that can be used to assess land health, prioritize land for restoration and rehabilitation, and assess outcomes of conservation practices and whether land use and management objectives are being met. A Rangeland Indicator Calculator (https://jornada-data.shinyapps.io/rangeland-indicator-calculator/ [Accessed 15 01 2025]) enables users to query or upload data and grouping variables to produce custom indicators of management interest.

Concurrent management for multiple ecosystem services, which is typical for rangelands, requires a broad set of indicators and the ability to assess their interactive responses to drought, climate change and disturbances, in addition to responses to management practices sought to improve the sustainability of rangeland social-ecological systems. Harmonizing and aggregating monitoring datasets has provided opportunities for the scientific community to develop, in partnership with pastoralists and managers, new indicators that can broaden data use in decision making, and to develop predictive models that extend the kinds of quantitative indicators available to users (e.g., wind and water erosion) and their spatial and temporal coverage through remote sensing applications (Jones et al. 2018; Allred et al. 2020). The Rangeland Hydrology and Erosion Model (RHEM) (Hernandez et al. 2017) and Aeolian EROsion (AERO) model (Edwards et al. 2022) were developed for standard monitoring data applications. Running the models on aggregated monitoring datasets has enabled public release of quantitative erosion indicators that are interpretable alongside other indicators of land health and biodiversity – transforming how soil erosion can be considered in management decisions across watersheds and airsheds (Webb et al. 2017). For example, AERO has been used to assess how invasive annual grasses can accelerate and suppress sediment transport across rangeland wind erosion hotspots depending on wildfire interactions (Tremino et al. 2024). Such models also present new opportunities to evaluate relationships between land degradation processes and the ecological dynamics of rangelands, with identification of critical eco-geomorphic thresholds providing a basis for identifying early warning indicators of ecological state change (Webb et al. 2024) and insights into where and why restoration practices are/are not likely to be successful (Schaeffer et al. 2025).

Data analysis and interpretation frameworks to build a shared understanding of ecosystems

Collecting standardized monitoring data provides a foundation for using data to inform adaptive management. However, interpreting data in a reproducible (and defensible) way can be challenging. Setting and applying benchmarks has emerged as a practical way that managers can interpret big indicator datasets and make objective and actionable decisions about rangeland management (Webb et al. 2020). Benchmarks have been defined as indicator values or ranges of values that establish goals for resource conditions, such as land health (Kachergis et al. 2020). Benchmarks can simplify data applications in adaptive management to 1) make land health assessments to determine whether objectives, standards, or regulations are being met; 2) identify and prioritize land for restoration treatments; 3) assess the efficacy of conservation practices, restoration, reclamation, and rehabilitation; and 4) compare management strategies to inform adoption of new management approaches (Webb et al. 2024).

A critical consideration for setting land use and management goals, and selecting management practices, is how effective they are likely to be given the land potential and ecological dynamics of a site. Using information about land potential is an effective way of establishing realistic benchmarks that reflect local ecosystem dynamics – including responses to drought, climate change, disturbances and management. Land potential describes the potential productivity, degradation resistance and resilience of sites as influenced by soil properties, climate and landscape position (Herrick et al. 2013). Ecological states represent contrasting land conditions as influenced by land management and climate variations interacting with land potential. Benchmarks can be established for monitored indicators by identifying indicator values that represent desirable ecological state characteristics. Benchmarks can also be set based on knowledge of thresholds between states at which certain processes, for example soil erosion, impact ecosystem function and result in state change. Collaborative benchmark setting involving natural resource managers, scientists and pastoralists has been an effective way of engaging managers (often for the first time) in exercises to interpret indicator datasets and think critically about their use to inform management on-the-ground. These activities have been supported by development of the Ecosystem Dynamics Interpretive Tool (https://edit.jornada.nmsu.edu/ [Accessed 15 01 2025]) and State Transition Classifier (https://webapps.jornada.nmsu.edu/transition-classifier/ [Accessed 15 01 2025]), which provides a global framework for developing and sharing state-and-transition models (STMs) (Bestelmeyer et al. 2016). Producing quantitative STMs, and establishing indicator value ranges for states and transitions, has become a major research interest to support big data interpretation in decision making to meet land use and sustainable development goals, avoid, reduce and reverse land degradation, and minimize spending on practices that are unlikely to be effective or have undesirable outcomes (Heller et al. 2022; Duniway pers. comment.).

Discussion: Big data-informed adaptive rangeland management

Building accessible knowledge systems from big data and digital tools is already having impact on management decisions, pastoralists livelihoods, and management outcomes on rangelands. Further improving data access will enable more insights that can increase capacity to adopt adaptive management approaches to avoid, reduce and reverse land degradation and support sustainability and planned transformation of rangeland social-ecological systems in the context of drought and climate change. By linking big monitoring datasets with models and interpretive tools that support applications of land potential concepts and benchmarks, simple workflows can be developed that enable pastoralists to prioritize actions based on their management objectives, local knowledge and data. One successful example is the Land Treatment Exploration Tool (https://www.usgs.gov/apps/land-treatment-exploration-tool/ [Accessed 16 01 2025]), which provides a one-stop-shop for managers to access historical land treatment data, monitoring indicators and erosion predictions from the Landscape Data Commons, remote sensing data on vegetation cover, and drought forecasts to plan rangeland restoration and rehabilitation. With such tools in hand, managers can use data to help identify resilient land and management options that support resilience, identify land at risk of degradation and loss of ecosystem function, and apply that knowledge to assess landscapes, learn from their condition and the outcomes of management actions, and adjust management where and when needed to meet land use and management goals. Early identification of where there are risks or threats to the status, condition and trend of rangelands can support identification of land use and management approaches that are sensitive to the drivers of ecological state transitions and assist pastoralists and other rangeland managers in anticipating and preparing for more systemic impacts of climate change.

Mind the gap: Integrating rangeland ecology into management requires more than just knowledge dissemination

Vetter, S[1]

[1]Department of Botany, Rhodes University, Makhanda 6140, South Africa

Key words: International Year of Rangelands and Pastoralists; knowledge co-creation; local knowledge; rangeland ecology; rangeland management

Abstract

Rangelands are social-ecological systems that provide multiple ecosystem services, including livestock production. To sustain the services rangelands provide, it is crucial to integrate rangeland ecology into their management. However, the reality is complex, as rangeland management reflects human choices and values, is informed by different kinds of knowledge, and is constrained or enabled by various policy, governance, environmental, social and economic factors. In this context, how can rangeland ecology contribute more effectively to sound rangeland management? For ecological knowledge to guide management, it must be communicated effectively, accepted as valid, and viewed as trustworthy. However, what constitutes "true" knowledge and appropriate management of rangeland systems is very often contested. Reconciling and integrating local or indigenous knowledge with scientific knowledge is important for a shared understanding of management challenges and solutions, but tends to be challenging and unfamiliar for both rangeland ecologists and land managers. Historical legacies and biases among researchers and land managers can also create significant barriers to the acceptance and implementation of new ecological insights. The inherent uncertainty and debate within ecology, while necessary for advancing knowledge, can lead to confusion or mistrust among managers and policymakers. Additionally, the management implications of ecological knowledge in a system may not align with the values, objectives, and perceptions of land users or decision-makers. Integrating rangeland ecology into management thus requires dedicated work and collaboration between scientists and practitioners at all stages of the process from identifying problems, through co-creating and integrating knowledge, to finding solutions.

Introduction

Rangelands are social-ecological systems that provide essential ecosystem services, including livestock production, biodiversity conservation, and carbon storage (Briske & Coppock 2023). Their long-term sustainability thus requires management based on appropriate ecological principles. Rangeland ecology and related ecological fields (e.g., vegetation dynamics, herbivore population and behavioural ecology) are well-developed, and much of this research is motivated by the need to understand and manage the ecological dynamics of rangelands better. Yet many rangelands across the globe and under a variety of tenure and management systems are described as mismanaged, degraded and vulnerable to global change, despite concerted efforts at informing, resourcing and developing their stewardship (UNCCD 2024). The long and ongoing debate around desertification in arid rangelands is a case in point, with powerful crisis narratives persisting and driving the policy agenda, and interventions aimed at stabilising inherently variable systems, despite mounting evidence that the reality is more nuanced (Behnke & Mortimore 2016). I argue that this disconnect is not simply a matter of communicating knowledge or educating land users, but reflects deeper issues related to how knowledge is produced, perceived, applied, and valued by different stakeholders. Scientific knowledge must not only be disseminated but also accepted, trusted, and considered relevant by those making management decisions Wilmer et al. 2021). Historical biases, institutional inertia, competing values and interests, and substantial power differentials between role players further complicate the process of integrating ecological knowledge into practice (Utter et al. 2021).

When rangeland ecology fails to inform appropriate management
A number of possible scenarios can account for misalignment between rangeland ecology and management. The first step towards better alignment is to identify which scenario we are dealing with, and the reasons for it.

1. Lack of uptake because the knowledge is flawed

There is a long and growing list of cases where the ecological knowledge guiding interventions is inappropriate to the local ecological dynamic, land users' objectives, or altogether. This includes applying models developed for different ecological contexts without testing their validity, or applying altogether outdated and disproven knowledge. For example, the notion that drylands are the result of deforestation by nomadic pastoralists, which resulted in their climate aridifying, was widely held in the 19th century (Davis, 2016). The solution was "reforestation" and other interventions such as irrigation to "green" the deserts. These actions have often caused salinization of soils, lowering of water tables, and invasion of fast-growing exotic tree species such as Prosopis. Ironically, more often than not the "solution" to the resultant resource degradation consists of more cycles of the same misguided interventions (Davis, 2016). Land users resist because the proposed interventions do not work in their context, or because scientists and policy makers make the wrong assumptions about problems that need to be addressed. Often the historical origin of these pervasive narratives has long been forgotten but careful analysis reveals flawed logic that has been transmitted uncritically over generations (Davis 2016; Davis and Robbins 2018).

2. The knowledge is sound, but it is not applied

This is often assumed to be the case when scenario 1 is actually the explanation. In other cases, however, the ecological dynamic and its management applications are well understood and agreed on, but not applied by land users. Possible reasons include lack of trust, or misunderstanding; but very often there are economic, institutional, policy and/or logistic impediments. For example, while flexible stocking approaches are ecologically appropriate in variable climates, the relative optimality of fixed vs tracking strategies depends on a range of factors including climate variability, access to markets, property rights regimes, market stability and prices (Campbell et al. 2006), and requires a supportive policy environment. Land users and policy makers may also prefer simple, rule-based approaches that aim for stability over adaptive strategies that require continuous monitoring and adjustment.

3. The knowledge is poorly supported but popular among land users and policy makers

When knowledge is poorly supported, land users are generally less likely to embrace it than policy makers and advisers; but there are examples where land users adopt management based on poorly or incompletely supported science. Again, reasons for such a scenario can vary. It may be a case of very persuasive and dedicated proponents or incentives. The practice may have proven successful in some contexts and applied in contexts where it is not appropriate; or rooted in tradition but no longer suited to current contexts.

For example, despite scientific criticisms, holistic planned grazing (Butterfield et al 2006) remains popular in many regions. Its compelling narrative offers a hopeful solution to land degradation, it aligns with ranchers' economic interests, and it appeals to conservationists and agriculturalists (Bennie et al 2024). Anecdotal success stories from individual practitioners have reinforced its credibility, even in the absence of consistent scientific validation (Hawkins 2017). The success of this approach in gaining widespread acceptance highlights the role of active promotion, personal experience, and economic incentives in shaping management decisions.

4. The appropriate solution is unknown or uncertain

Sometimes management problems defy current understanding of the system. Fires are known to suppress woody vegetation, yet a regularly burned rangeland is steadily becoming more encroached. An invasive species has taken over and nothing seems able to bring it under control. Years of resting have failed to improve the condition of a rangeland dominated by unpalatable grasses and shrubs. Often the reason is that the situation is novel – for example, elevated atmospheric CO_2 has changed the frequency and intensity of disturbance required to suppress shrubs (Bond & Midgley 2012; Ripley et al. 2022), and the formerly open grassy vegetation would require management actions that are no longer feasible or economical.

When rangeland ecology informs management

For all of the above possibilities, there is also the possible – and ideal – scenario that the available knowledge is ecologically sound and is applied successfully, whether in the form of a traditional system that has managed to maintain its desired features, or in the form of management consciously adapting in response to changing conditions and scientific input. This raises the question of what the factors are for success, especially if applying such knowledge means changing land users' practices substantially.

In the ideal scenario, the land manager understands and trusts the proposed management actions, a scenario that becomes more likely if they played an active role in identifying the problem and co-producing the knowledge underpinning the solutions (Wilmer et al 2021). This scenario is also more likely if management draws on land managers' existing practices and own knowledge, or is at least compatible with their knowledge system, and less likely if the management intervention is provided by outside experts with little local knowledge. Local knowledge can also help bridge separate and at times antagonistic fields of scientific knowledge, as in a case where herders' knowledge of cattle foraging behaviour helped integrate rangeland ecology (concerned with animal nutrition) and conservation ecology (concerned with avoiding biodiversity loss) by developing herding strategies that harmonized these different objectives (Molnár et al 2020).

The inherent uncertainty and debate within ecology, while necessary for advancing knowledge, can lead to confusion or mistrust among managers and policymakers. Success in solving management problems is more likely if risk and uncertainty are (or are perceived to be) low, or at least balanced by the benefits; land users in an already precarious economic situation, and who lack reliable safety nets are likely to be more risk averse and wary about adopting management practices that they have no direct experience of. Land users who have the agency and resources to implement the changes are more likely to adapt and succeed; communally managed rangeland with poorly functioning governance institutions, or where conflicts over land use exist, face much greater challenges, especially where factors such as dispossession, resettlement or constraints to mobility have heightened local conflicts over resources (Vetter 2013).

Ideally, management actions yield benefits quickly, providing the feedback that stimulates their continued implementation. The unpredictable and climatically variable nature of many rangelands tends to obscure trends and can cause setbacks (or apparent success in a good year that is not sustained in other years) and this can make evaluating and adapting management challenging. Rangeland ecologists can draw on data and literature from long-term studies to provide evidence while designing local studies and the communication around them in ways that are appropriate to their dynamic nature.

Integrating knowledge systems, knowledge co-creation and transparently negotiating trade-offs

Despite this complexity, a few general important lessons emerge.

1) It is important to be clear about the objective(s) of the land management and to ensue that the solutions actually aim to achieve these. This requires a common shared understanding of the social and ecological dynamics and constraints of the rangeland system, and achieving this requires sustained engagement, trust, and knowledge co-creation (Wilmer et al 2021).

2) Trade-offs are inevitable (e.g. plant biodiversity vs beef production vs carbon sequestration) and need to be transparently addressed. Misleading narratives of unrealistic win-win scenarios may impress donors and the

global public but can leave pastoralists losing out to carbon forests or "fortress" conservation (Fleischman et al. 2021).

3) Different stakeholders and role players often have very different objectives and understandings of the ecological dynamics of the system; differentials in economic and political power often influence which objectives and paradigms hold sway, and these are very often not the pastoralists' own objectives or knowledge system, leading to failed or unsuccessful implementation (UNCCD 2024).

Reconciling and integrating local or indigenous knowledge with scientific knowledge is important for a shared understanding of management challenges and solutions, but tends to be challenging and unfamiliar for both rangeland ecologists and land managers. Rangeland users – such as pastoralists, ranchers, and indigenous communities – rely on experiential and traditional knowledge systems that may differ from scientific interpretations. These knowledge systems may be rooted in cultural practices and long-term observations of the land, but which almost everywhere have had to adapt to drastically changing circumstances including climate change, land dispossession, restriction of mobility, stock reduction schemes and other interventions. Successful integration of ecological insights into practice thus requires active collaboration starting with problem identification, an openness to multiple knowledge systems, and an appreciation for the values and constraints that influence land users' choices (Utter et al. 2021; van Ewijk and Ros-Tonen 2021). The International Year of Rangelands and Pastoralists (IYRP) aims to address these issues, through raising awareness of the diversity and value of different pastoralists systems, and by giving greater voice and prominence to pastoralists and the organisations that represent and support them.

Rangeland conservation: courage and resiliency in the face of climate adversity

Molesworth, A

Australian National University, Anika.Molesworth@anu.edu.au

Keywords: Rangelands; ecosystems; climate change; resiliency; courage

Abstract
As climate change continues to impact rangelands worldwide, threatening the livelihoods of millions and the ecological integrity of these vital ecosystems, community-driven action has emerged as a powerful force for building resilience. Adapting to and mitigating the effects of climate change on rangelands requires courage from individuals and larger society and determination to overcome these challenges and drive positive change.

The integration of innovative management practices and technologies is essential for enhancing the resilience of these ecosystems. Digital technologies, such as monitoring databases, mobile applications and AI power, offer new insights and a way to enable land managers to adaptively manage rangelands amidst rapid changes. However, empowering communities to lead rangeland adaptation requires more than just technical solutions. It requires a fundamental shift in how we approach conservation and development, one that values local voices, respects traditional knowledge, funds research in region that are not deemed 'profitable', and fosters sincere partnerships embedded with trust and mutual learning. Courage and resiliency are crucial – to challenge entrenched power structures, to embrace uncertainty and experimentation, and to work in solidarity with local rangeland communities that are on the frontlines of these challenges.

It is time we welcome a new paradigm for rangeland management – one that recognises the value of these ecosystems goes far beyond economics, the inherent resilience of local people, and the transformative power of collective ambition to take care of precious rangeland environments.

Rangeland Significance
Rangelands represent far more than agricultural landscapes or locations for extractive industries – they are critical ecosystems that teem with biodiversity when in a healthy state, and that require shared stewardship and collective responsibility for their future. These vast territories, covering approximately 30-40% of Earth's land surface and supporting 1-2 billion people (Sayre et al., 2013), embody the intricate relationship between human communities and natural systems. Yet, despite their extent and importance, rangelands are often neglected in research and funding for development, whilst becoming increasingly vulnerable to climate change due to their low and variable rainfall, and poor soil fertility.

In Australia, rangelands occupy about 70% of the country, approximately 6 million km^2 (Guerin et al., 2017). Many rangelands support pastoral activities, contributing significantly to global food security (Herrero et al., 2016). They hold critical importance to global ecosystem services, including carbon sequestration and biodiversity conservation (Sala et al., 2017).

Climate Change and Rangelands

For rangeland managers, climate patterns form the cornerstone of decision-making processes. Temperature and rainfall guide crucial determinations on stocking rates, grazing rotations, and land management strategies (Briske et al., 2015; Eldridge and Beecham, 2018). This dependency on natural rhythms makes the disruption of traditional climate patterns particularly concerning for rangeland communities. Increasingly, generational knowledge passed down through communities no longer aligns with current conditions. These observations are validated by scientific evidence: anthropogenic greenhouse gas emissions have disrupted global climate systems, with rangelands experiencing warming at rates above global averages (IPCC, 2022).

Rangeland managers, working in close connection with natural systems, serve as front-line witnesses to climate change impacts. Rising temperatures manifest in more frequent and heatwaves, while increased evaporation hastens soil moisture loss, leading to droughts (Howden, 2017). Due to the ancient and weathered nature of Australian soils, rangelands are particularly susceptible to degradation processes such as erosion, compaction, salinization, acidification, and contamination, ultimately leading to fertility loss, increased desertification, and thus a decline in agricultural production and food security, which are exacerbated by climate change (Dadzie et al., 2023). Native vegetation communities are shifting in rangelands, affecting livestock nutrition and habitat availability for native species (Godde et al., 2020). These disruptions are reshaping viable agricultural activities across regions. Globally, mounting pressures on rangeland communities drive rural-to-urban migration, deepening socioeconomic inequalities among those who maintain these vital landscapes (Herrero et al., 2016).

The implications extend far beyond local communities. Rangelands function as crucial carbon sinks, storing approximately 30% of global soil carbon (Wang et al., 2016), while serving as biodiversity hotspots and essential components of global food security. Their deterioration threatens not just local livelihoods but larger planetary health. In recent decades, rangelands worldwide have faced mounting pressures from climate change, overgrazing, feral animal explosions and other land-use changes. Human-driven degradation of the Earth's land surface is affecting the well-being of over 3.2 billion people, accelerating the planet toward a sixth mass extinction of species, and leading to biodiversity and ecosystem service losses amounting to over 10% of the annual global GDP (IPBES, 2018).

Courage for Rangeland Conservation

A central challenge emerges: how can societies simultaneously achieve good ecological health and community resilience in rangelands? One answer lies in cultivating what can be termed "climate courage" - the moral and practical strength to confront and act against climate change challenges, despite the uncertainty and anxiety they invoke. This concept encompasses both individual determination and collective action, building on social-ecological resilience (Folke et al., 2016). Climate courage moves beyond mere adaptation to actively promote positive environmental change, positioning planetary health as a central determinant in decision-making and action. It manifests through community-driven initiatives that combine traditional knowledge with innovative solutions, fostering resilience while acknowledging the deep interconnections between human wellbeing and ecosystem health.

The relationship between humanity and the biosphere is fundamentally reciprocal - we shape our environment and it in turn shapes us. This interconnection has led to growing recognition that development strategies and scientific research must account for the deep links between human welfare and the health of our planet's living systems, as exemplified in frameworks like the Sustainable Development Goals. By viewing these challenges through the lens of interlinked social-ecological resilience, we see that human development must be grounded in and compatible with the biosphere's capacities and finite resources (Pedro et al., 2024). The recognition of our dependence on Earth's living systems will help in stewarding human development in harmony with the biosphere - a crucial requirement for both sustainable development and maintaining human dignity, particularly in fragile rangeland ecosystems.

The magnitude and urgency of climate change impacts on rangelands demand more than incremental responses or business-as-usual approaches. Climate courage means acknowledging that conventional management practices and policy frameworks are insufficient for the challenges ahead. It requires embracing transformative changes in how we manage, value, and protect these landscapes. This includes supporting innovative practices that may challenge current approaches, advocating for policy changes that prioritise long-term sustainability over short-term productivity, building new partnerships that bridge the divide between scientific and traditional knowledge systems, and supporting community-led co-creation (Lavhelesani et al., 2024).

Looking to the Future

The path forward demands a fundamental shift in how we think about rangelands and their management approaches. We must move beyond viewing these landscapes solely through the lens of production or extraction, recognising their vital role in climate regulation, biodiversity conservation, and cultural heritage (Stafford Smith et al., 2020). To appreciate these precious landscapes and look after them in the manner required, there must be empowered local communities who are active decision-makers, who integrate traditional and scientific knowledge, and who build supportive networks that transcend individual properties to catchments and outwards to reach business and policy.

Success are stories are emerging. Pastoral networks share knowledge about drought-resistant native species and innovative water management techniques, improving resilience to climate variability (Marshall et al., 2018). National Drought Resilience Adoption and Innovation Hubs have been established to help with this. The national farmer movement, Farmers for Climate Action, exemplifies climate courage, uniting farmers and agricultural leaders across Australia to advocate for climate solutions while building resilient farming communities. There are research teams working in remote rangeland locations. The Wild Deserts field site, covering 35,000 ha in north-west New South Wales, aims to bring back seven locally extinct mammals. Similarly, Arid Recovery, an independent not-for-profit running a 123 km^2 wildlife reserve in South Australia's arid north, is pioneering conservation science to help threatened species thrive across the Australian outback. Nearby, Boolcoomatta is a 63,000 ha former sheep station now conservation reserve.

One more controversial topic in Australia's rangeland management is that of dingos. Recent studies suggests that dingoes, Australia's largest terrestrial predator, can play a crucial role in maintaining healthy rangeland ecosystems while potentially increasing profits for farmers. Dingoes suppress populations of kangaroos and feral animals, reducing unmanaged grazing pressure that contributes to landscape deterioration (Campbell et al., 2022; Letnic et al., 2013). This effect from dingo presence can lead to increased pasture biomass, improved livestock condition, and higher profit margins for pastoralists (Prowse et al., 2015; Pollock, 2021). Additionally, dingoes may indirectly benefit small mammals and vegetation by controlling invasive species like foxes and cats (Letnic et al., 2013; Newsome et al., 2015). While dingo reintroduction has been proposed to restore degraded rangelands, it remains controversial due to concerns about livestock predation and conservative community views (Newsome et al., 2015). This is indeed an area for further research and community education – coupled with courageous conversations – so that there is greater understanding of dingoes' ecological impacts and to develop management strategies that balance predator conservation with livestock production.

These are just some of the many examples and areas for research throughout Australia's rangelands that are both encouraging and inspiring and that are helping to protect rangelands in our climate challenged world.

Conclusion

Despite the grand and complex challenge that climate change presents, there are people who are stepping up and speaking out to look after rangelands. Climate courage means facing hard truths about environmental change while taking decisive action. This type of courage isn't just about bravery or rose-tinted optimism - it's about maintaining hope and taking practical action in the face of serious environmental challenges, all while preserving the cultural and ecological heritage of rangeland systems now and for future generations.

Securing a resilient future for rangelands requires cultivating climate courage within individuals and communities. It depends on us truly acknowledging our dependence on healthy, thriving natural ecosystems and the relationship of reciprocity. This determination to care for the planet's precious rangelands can radiate from local initiatives, the amplification of traditional knowledge, the embracing of innovation, and fostering collective resilience in the face of change. Through coordinated action and shared determination, communities can enable positive transformation in rangeland management and conservation.

Modifying the education system for children of migratory pastoralists of Jammu and Kashmir State of India for equitable growth

Neetika, S[1]

[1]Government Middle School, Bari brahmana, District Samba, 181133, Jammu and Kashmir, India

Key words: migratory pastoralists, education system, mobile schools, equitable growth

Abstract
Children whose elders are actively engaged in pastoralism are becoming more and more demanding when it comes to their schooling. Poverty-stricken households view education as a means of escaping their situation, whereas pastoralist households view it as a means of sustaining their system of production in a world that is becoming more interconnected. Education systems, on the other hand, are still focused on "educating pastoral children out of pastoralism" and are failing to adapt to this change in demand. Programmes for education intended for sedentary individuals are typically expanded to include pastoralists, and they are predicated on a straightforward modification of sedentary models to account for some elements of nomadic living. The greatest transhumant population in the world is found in Jammu & Kashmir. The *Gujjars* and *Bakarwals* make up the majority of the population in this part of the Himalayan valley and are the third largest ethnic group there. *Bakarwals* are people who herd sheep and goats, whereas Gujjars raise big ruminants like cows and buffaloes. The *Chopan*s are a group of semi-nomad people who traditionally raise sheep in Kashmir for their meat and wool. For four to six months, the pastoralists migrate to the southern regions of the state, where they can find suitable climate conditions for their livestock to graze. Their children's education is their main issue because of the disparities in the curricula. A study was conducted on the possibility of opening mobile schools to provide children from migrant populations with a uniform education. Children from mobile schools outperformed those from stationary schools in terms of intellect. When compared to sedentary schools, the dropout rate from mobile schools was noticeably lower. In addition, a number of other socio-economic and ecological factors were investigated for overall welfare of the ethnic groups.

Introduction
Pastoralists have had difficulty sustaining their way of life (Waller 1999). They are traditionally semi-nomadic and nomadic herders who rely on their livestock as a source of income, cultural prestige, and sustenance (Gustafson et al. 2011, Lybbert et al. 2004). Although pasture and water availability has received much of the attention in research on the drawbacks of the traditional pastoral system, education for children is also essential to sustained livestock production and livelihoods. The need for education is growing quickly among pastoralists, particularly children who work directly in the field. In an increasingly globalised society, households actively engaged in pastoral production saw education as a means of sustaining their production system, while impoverished households view it as a means of escaping poverty (Siele et al. 2011). However, educational systems continue to focus on "educating pastoral children out of pastoralism" and through formal schooling, failing to adapt to this change in need. Education programmes for pastoralists are often based on a straightforward adaptation of sedentary models to certain characteristics of nomadic living, and they are typically an extension of those created for sedentary people. Productive households are thus forced to choose

between continuing the family business and obtaining access to formal education, which is a detrimental trade-off. Historically, pastoralists have been marginalised. "The greatest poverty rate and the least access to essential social services are found in nomadic pastoral areas (Allen 2017)". Therefore, a study was conducted to examine the significance of mobile schools for the children of pastoralist Mobile schools were established by the Jammu and Kashmir government for children from pastoral families, however they are only operational for around six months during the winter when pastoralists are not at home. Short-term teachers receive a set wage that is significantly less than that of their permanent counterparts.

Methods

A study was conducted on the possibility of opening mobile schools to provide pastoralist children from migrant populations with a uniform education. As a case study, 50 pastoralist children were selected, at random, 25 each from mobile and stationary school. The study was conducted from 2019 to 2023 for five years. Both formal and informal questionnaires were utilized to gather information from the elders, temporary teachers, and schoolchildren about the pastoralists' migration and educational system. To gain a thorough understanding of the migratory system, previous research publications and existing literature were examined.

Results

Dropouts and passing rates

The findings revealed that, compared to mobile school children, the number of dropouts among pastoralist schoolchildren was substantially greater if they were stationary schoolchildren (Fig. 1). Children attending mobile schools tended to pass more often (Fig. 2). It was discovered that the dropout rate for children attending mobile schools was one student in each of classes three and four, and two in class five. In contrast, at the class 2, 3, 4, and 5 levels, the dropout rates were 1, 8, 3, and 8 pupils, respectively, in sedentary schools. In mobile schools, the passing percentage was 100, 98, 96, 92, and 90, whereas in sedentary schools, it was 100, 96, 76, 68, and 50. Children who dropped out of school were viewed as failing pupils.

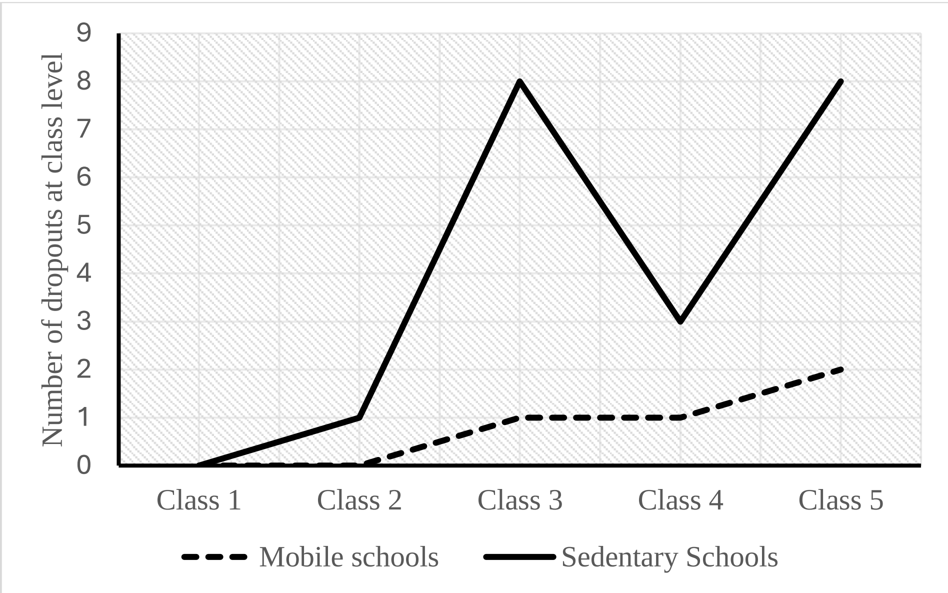

Fig. 1. Number of dropouts at class level

New mobile schools

The state government began mobile schools, though they are still in their infancy, after realising the difficulties faced by pastoralist schoolchildren. According to the information that is currently available, the guidelines in this regard are as follows: (i) the teacher will be an educated member of the moving tribe with the highest qualification; (ii) he or she will receive INR 10,000 as a salary for only six winter months; (iii) the teacher should have his own livestock and move with the other tribe members; and (iv) the government will provide a tent, a table, a chair, a mat, and books to facilitate the teacher and the students at the start of the session. It was also difficult for the parents to leave their kids emotionally and without proper care at home. Because there were no mobile schools, the kids who accompanied their parents didn't go to school. Many studies show that the domination of the school-based system itself is to blame for the historically dismal record of offering pastoralists access to high-quality education.

Major constraints

Parents, teachers, and school children brought attention to the challenges they encounter while switching from mobile to stationary schools, and vice versa. The main limitations were things like different curricula, dealing with new teachers, admissions processes, altered school environments, etc

Discussion [Conclusions/Implications]

The primary cause of the increased dropout rate among children of mobile pastoralist from sedentary schools was their insistence on going with their parents when they moved to the plains in the winter. Leaving their children at home, emotionally and without adequate care, was difficult for the parents at the same time. In the lack of mobile schools, the children who went with their parents did not pursue further education. A large body of research indicates that the historically poor record of providing pastoralists with access to high-quality education has been caused by the dominance of the school-based system itself. To date, the school-based system's structure and culture have been restricted to the "classroom" model of instruction and have not provided education as an alternative to pastoralism. A needless obstacle to learning is created for children in pastoralism by school-based services. They do not, however, want to replace pastoralism or undermine it because of its basic requirements. There isn't currently a service supply to meet this type of demand. This must be adjusted.

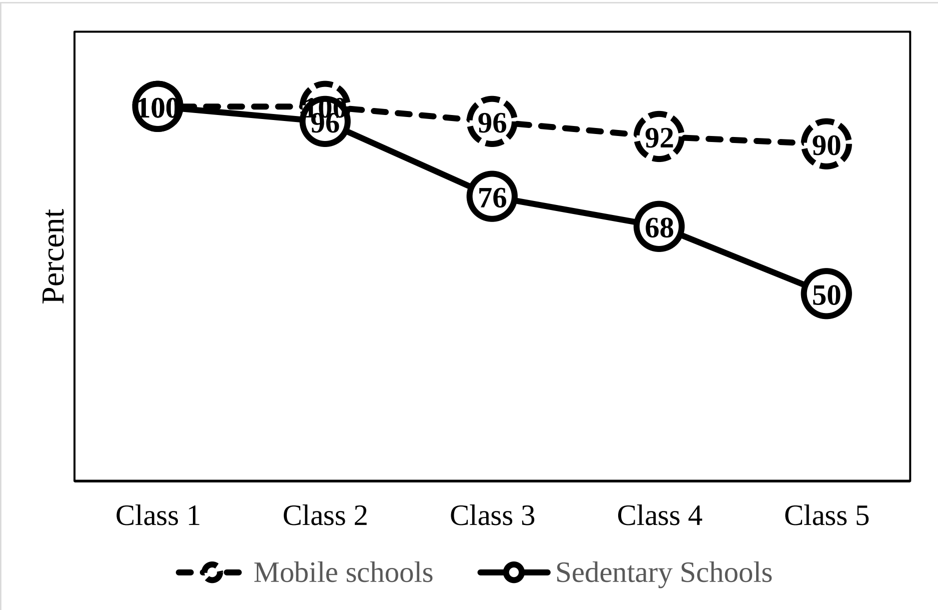

Fig. 2. Passing rate from mobile and sedentary schools
Note: Considered dropouts also.

A deeper comprehension of the role that mobility plays in pastoral production is necessary for effective educational inclusion measures. This must entail avoiding the disadvantageous trade-offs pastoralists face when their sole choice for obtaining "modern" education is a school-based model of provision that requires them to make concessions with pastoral produce and eliminates their means of subsistence within pastoralism. Instead of creating new avenues for advancement, this strategy restricts them. Putting the blame on pastoralists for their poor school attendance has diverted policymakers' attention from the fact that the educational system is, by definition, keeping prospective students out of the pastoral system.

Key words: authentic inquiry; STEM education

Abstract

The Prairie Project aims to promote pyric herbivory and mixed species grazing as climate-smart agricultural practises for sustaining livestock production and other ecosystem services of rangelands in the Great Plains. Key to fulfilling such a shift of management paradigm is effectively engaging land managers and professionals, future professional and decision makers, and the public through integrated research, education, and extension efforts. Leveraging citizen science as an effective tool for research and education and outreach through crowdsourcing, we have been developing citizen science projects on the Zooniverse platform for engaging secondary and undergraduate students as well as the public, based on research data collected at our research and demonstration ranches across the Great Plains. In one of these projects, students and the public engage in identifying animal species and their activities as captured on camera-trap photographs from a research ranch. The data generated are essential for studying the spatial and temporal distributions and behaviour of livestock and wildlife in different vegetation communities and with different burn histories. Crowdsourcing the data classification also presents educators with a platform for designing and implementing high-impact learning activities in classrooms and extension programs. Importantly, this also allows us to reach a broader and more diverse audience outside the traditional range management and ecology community. We have developed and implemented learning activities in an introductory ecology course at a research university and are developing learning activities for additional educational settings. During the last two years, over 950 students have engaged in this Zooniverse project as part of an authentic inquiry project to explore the effect of fire on animal distribution and behaviour in different vegetation settings and developing critical thinking and communication skills. Assessment data show that these experiential learning activities resulted in significant gains in understanding the scientific practice and rangeland literacy.

Introduction

The future of productive rangelands requires management practices that promote conservation of systems and education on the importance of rangelands for agricultural products and ecosystem services. The expansion of woody plants into grasslands of the North American Great Plains is a threat to the productivity, biodiversity and function of these rangelands (Archer et al. 2017, Londe et al. 2022). A secondary concern is the challenges presented by a growing urban population making policy decisions affecting rangelands (Sayre 2023).

The Prairie Project is a collaboration among researchers and extension specialists from the University of Nebraska-Lincoln, Oklahoma State University, and Texas A&M University. The project aims to increase the ecological and economic production of Great Plains rangelands by combatting woody plant encroachment with pyric herbivory and multispecies grazing. As part of the research into the effects of these treatments, we have placed camera-traps on a research ranch in Texas to record the movements of livestock and wildlife. To assist us in classifying the animals and their activities, we have employed the public through the citizen science platform Zooniverse. Photographs are grouped into six categories based on the locations' burn status (burned or unburned) and vegetation community (herbaceous-dominated, small woody-dominated, or large woody-dominated).

Authentic inquiry-based learning engages students by allowing them to investigate real-world, open-ended problems using critical thinking and the research process (Crawford 2000, Herrington and Kervin 2007, Krajcik and Blumenfeld 2006). To this end, we have developed a Zooniverse-based authentic inquiry activity for students of an introductory ecology class at an R1 university. We investigated the effectiveness of this activity by analyzing students' self-assessments on interest, ability, and knowledge of ecology and the scientific process (Wu et al. 2021).

Methods

The activities of this inquiry-based project were given to students of an introductory ecology course titled 'Fundamentals of Ecology' at Texas A&M University in the fall semesters of 2022 and 2023. This sophomore-level class has enrolment of 400 – 500 students. During the first week, students were taught the concepts of pyric herbivory and multispecies grazing and their use in combatting woody plant encroachment and increasing quality forage production. They learned about the study site and were assigned 100 photo classifications through the Prairie Project Zooniverse page. Students completed a survey by rating themselves on the following prompts on a Likert scale of 1 (very low) to 5 (very high): 1) interest in ecology, 2) ability to formulate a testable hypothesis, 3) understanding of the research process, and 4) ability to evaluate a scientific report. Working individually, students began identifying patterns in the photographs during the second week to develop a testable hypothesis and design the needed methodology to gather evidence to test their hypothesis. Students collected and analyze their data and submit a report during week 3. Peer reviews were conducted during the fourth week followed by revisions and final submissions during the fifth week. The project concluded with students again rating themselves on the same survey.

To test students' self-perception of learning, we analyzed pre-project and post-project responses to survey questions using a Wilcoxon signed-rank test. We evaluated effect size using Cliff's delta with the measures of $\delta = 0.11$, 0.28, and 0.43 to indicate small, medium, and large effect sizes, respectively (Vargha and Delaney 2000). Additionally, we applied Wilcoxon signed-rank test for each survey question by student categories. These groupings were male and female students, upperclass and lowerclass students, underrepresented minority students (URM) and other students (non-URM), and students taking the course as a degree requirement (major) or science elective (non-major). For purposes of this study, first- and second-year students were classified as lowerclass and students in their third year or beyond were classified as upperclass. Students from university departments of ecology and conservation biology; rangeland, wildlife, and fisheries management; environmental studies; landscape architecture; and recreation, park, and tourism sciences were required to complete this course. Finally, Hispanic, black, American Indian, mixed race or ethnicity, and international students were classified as underrepresented minorities. We used Mann-Whitney U-tests to detect differences in learning gains (calculated as pre-survey response subtracted from post-survey response) between male and female students, upperclass and lowerclass students, URM and non-URM students, and major and non-major students. Again, we evaluated effect size using Cliff's delta.

Results

A total of 568 students consented to participating in our study during the autumn 2022 semester ($n = 325$) and the autumn 2023 semester ($n = 243$). Based on our demographic groups, there were 231 male and 337 female students and 199 URM and 369 non-URM students. There were 248 upperclassmen, 320 lowerclassmen, 369 major students, and 199 non-major students.

Overall, students' interest in ecology did not differ between pre-survey and post-survey responses ($W = 3572.5$, $p = 0.9112$). We detected significant differences in students' ability to formulate a hypothesis ($W = 5687$, $p <$

0.0001), understanding of the research process (W = 2737, $p < 0.0001$), and ability to evaluate a scientific report (W = 5353.5, $p < 0.0001$). Effect size for these responses were medium (δ = 0.387), large (δ = 0.551), and medium (δ = 0.429), respectively.

When broken into groups, we again did not detect a difference between pre-survey and post-survey responses for students' interest in ecology (Table 1). Differences were detected across all groups for the remaining survey responses. All groups exhibited a medium effect size for hypothesis formulation except male students with a small effect. A large effect size was observed across groups for understanding the research process. Finally, all groups exhibited a medium effect size for evaluating scientific reports except female students with a large effect.

Table 1. Differences in students' self-perception of learning before and after participation in an authentic inquiry project as tested by Wilcoxon signed-rank test (W) with effect size measured by Cliff's delta (δ).

Student Group	Interest in ecology			Ability to formulate a hypothesis			Understanding of the research process			Ability to evaluate a scientific report		
	W	*p*	*δ*	*W*	*p*	*δ*	*W*	*p*	*δ*	*W*	*p*	*δ*
Male	1695	0.858	0.001	1735.5	<0.001	0.315	652.5	<0.001	0.538	1082	<0.001	0.357
Female	3234	0.754	0.009	893.5	<0.001	0.437	676	<0.001	0.558	1577	<0.001	0.480
URM	1535.5	0.676	-0.003	734.5	<0.001	0.386	297.5	<0.001	0.556	526.5	<0.001	0.466
Non-URM	3469.5	0.643	0.010	2340.5	<0.001	0.388	1222	<0.001	0.548	2535.5	<0.001	0.409
Upperclass	1345.5	0.434	0.021	1386.5	<0.001	0.356	689.5	<0.001	0.511	1268	<0.001	0.388
Lowerclass	3615.5	0.622	-0.006	1405.5	<0.001	0.416	648	<0.001	0.581	1389	<0.001	0.462
Major	4623	0.804	-0.002	2380.5	<0.001	0.400	1116	<0.001	0.572	2691	<0.001	0.431
Non-major	905	0.582	0.022	711.5	<0.001	0.364	358.5	<0.001	0.512	458.5	<0.001	0.427

None of the results of the Mann-Whitney U-tests showed a significant difference between learning gains of any of the groups across all 4 survey responses.

Discussion

Assessment showed that participation in this authentic inquiry project promoted students' self-perception of learning the scientific research process. This methodology has been shown to promote knowledge retention and academic performance in the STEM fields, enhance student engagement and motivation, supports development of self-regulated learning, and increases student confidence in their academic abilities (Savery 2006, Zimmerman 2002). Furthermore, inquiry-based learning promotes systems thinking in ecology and can inspire students to engage with ecological issues (Gormally et al. 2009, Tanner 2009).

By using our citizen science project on Zooniverse, we were able to provide students with exposure to actual data from research in a rangeland setting. The course curriculum provided a wide-range of students with lessons in rangeland ecology, management practices, and problems facing rangelands. The majority of the students taking this course do not study rangeland ecology and management nor come from rural backgrounds or demographics of past rangeland managers. Thus this is an important outreach interface. Rangeland literacy can promote positive outcomes by educating voters and future policy-makers whose decisions often affect the stewardship of these lands (Launchbaugh et al. 2012). Two noteworthy challenges to current rangeland curriculum include shifting demographics and organizational shifts within university programs (Tanaka et al. 2012). Our results indicate that we were able to provide rangeland literacy across all demographic groups from an introductory ecology course not housed within a rangeland ecology and management department.

Bridging academia and outreach: mentorship programs for future rangeland scientists

Ehlert, KA[1]; Brennan, JR[2]; Menendez, H[2]; Johnson, P[2]

Key words: Extension, framework, graduate students

Abstract

Integrating graduate students into mentorship programs that encompass teaching, research, and Extension/outreach is essential for developing a skilled workforce capable of addressing the multifaceted challenges of rangeland management. Although many graduate programs focus on developing academic skills necessary to conduct rangeland research, students often enter the workforce unprepared to engage with diverse stakeholder groups that comprise the rangeland community. We explore how outreach specialists can collaborate with academic researchers to create deliberate, comprehensive mentorship frameworks that enhance graduate education and professional development. This paper directly responds to Theme 2 of the 2025 International Rangeland Congress as we present a model that involves a synergistic approach to incorporating stakeholder engagement with student training. Specifically, this model integrates the expertise of outreach specialists, who provide practical, field-based insights, with academic researchers, who contribute theoretical and methodical rigor. The resulting collective collaboration ensures that graduate students gain a holistic understanding of rangeland science, encompassing both traditional and innovative practices. Critical components of the mentorship program are 1) co-designing research projects that address real-world, producer-driven problems, 2) engaging students in community-based outreach activities, and 3) fostering partnerships with local stakeholders. The hands-on approach both enhances students' technical skillsets and builds capacity for effective communication and collaboration - essential for future leadership roles in rangeland management. By embedding graduate students in multidisciplinary teams and providing opportunities for participatory research, this mentorship model aims to strengthen the academic-research-outreach paradigm and further embed graduate students in the rangeland community. A holistic mentorship approach ultimately contributes to more resilient and sustainable rangeland outcomes and prepares the next generation of rangeland scientists to tackle the complexities of global rangeland ecosystems.

Introduction

Rangeland science can address some of the most pressing global challenges, including food security, climate change adaptation, biodiversity conservation, and sustainable land use. Rangelands cover 54% of the global terrestrial surface, amounting to approximately 79.5 km^2 (Rangelands Atlas 2021). Consequently, they support key ecosystem services (Macfadyen et al. 2012) such as carbon storage, wildlife habitat, and water filtration, while simultaneously providing a foundation for livelihoods based in agriculture. Effective management of rangelands is critical, then, and requires science and practice to be integrated to address complex challenges and "wicked" problems, from climate change to biodiversity loss.

Although rangelands have a significant role in global sustainability, a gap exists between academic research and practical application. The results from research generated by universities and research institutes can sometimes stay in the "ivory tower" and fail to reach practitioners, policy makers, and local stakeholders who depend upon and manage rangelands across the globe. Contributing factors include limited communication among groups, different priorities between academics and managers, and limited training opportunities that integrate outreach and applied applications. Consequently, it is important to bridge this divide to ensure that rangeland science effectively addresses real-world challenges.

Mentorship programs create the potential to serve as the crucial bridge between academia and outreach, helping to prepare the next generation of rangeland professionals to apply their knowledge in practical settings. Mentorship – the guidance of a less experienced individual (mentee) by an experienced professional (mentor), creates a collaborative framework for knowledge transfer, skill development, and professional growth (Allen et al. 2004). Within the context of rangeland science, mentorship can connect students and early-career professionals with experienced researchers, outreach specialists, and land managers, fostering a well-rounded understanding of both scientific principles and their application in diverse landscapes.

This paper explores the role of mentorship programs in bridging the gap between academia and outreach in rangeland science graduate education. We first examine the challenges that contribute to the academic-outreach divide, and then discuss gaps in rangeland graduate curriculum. Finally, we offer recommendations for designing and implementing mentorship programs that are tailored to the unique needs of rangeland science. By integrating cross-disciplinary mentorship into the broader framework of professional development, the field can cultivate a workforce that is not only scientifically literate, but also skilled in outreach, communication, and collaborative problem-solving.

Challenges Between Academia and Outreach

Several challenges are inherent when discussing the disconnect between academia and outreach in rangeland science. Among them are divergent priorities and goals, communication barriers, a perceived disconnect between theory and practice, time and resource constraints, the complexity of rangeland systems, and a decline in integrating traditional ecological knowledge (TEK). Academics tend to prioritize research advancements, publishing peer-reviewed articles, and securing grant funding. This can result in not fully understanding the needs of stakeholders, such as helping them adapt to climate change (Briske et al. 2015). Further, the pressing needs of stakeholders may not align with those outlined in funding requests for applications (RFAs). Communication between academia and outreach can be fraught, with research findings often published with technical jargon. Reed et al. (2014) examine principles for effective knowledge exchange in environmental management and suggest that knowledge exchange needs to be designed into research questions; the needs of both academics and stakeholders should be systematically represented in research; and finally, that long-term relationships must exist and be built on trust to construct a dialog between academics and stakeholders to ensure co-generation of new knowledge. Drawing parallels to rangeland science, if both academics and outreach professionals incorporate these principles, together they can increase the cross-pollination needed between theory and practice.

This cross-pollination can be hindered by time and resource constraints, as well as the complexity of rangeland systems, and lack of TEK. For example, faculty members are tasked with balancing research, teaching, advising, and service, leaving little time for outreach. Outreach is often underfunded and understaffed, leading to reduced capacity to facilitate knowledge transfer between academia and stakeholders. Further, granting agencies usually do not require outreach, reducing the impetus to include it in proposals. Thurow et al. (2007) explain that in the United States, a shift has occurred in funding from a baseline support formula to one that relies on competitive research grants that don't support management-oriented research. Engle and Wailer (1993) express frustration that the increase in competitive grant funding moves rangeland professionals away from long-term research priorities and instead has them focus on grantor priorities. In addition, rangeland systems are complex and face many "wicked problems," such as invasive species and climate change (Briske et al. 2015); this can result in disciplinary silos instead of cross-pollination between research groups. Lastly, modern research can overlook TEK, despite it being developed throughout time with rangeland systems (Berkes et al. 200). This can result in stakeholder groups feeling that academics are untrustworthy and further reduces collaboration between academia and local communities.

Gaps in Rangeland Science Curriculum

Research to date of rangeland science curriculum is not exhaustive; however, the research and commentaries that do exist underscore the need for a more comprehensive education that includes formal mentorship and collaboration between academia and outreach. Buckhouse and Powell (1985) express that undergraduate students in rangeland resources at Oregon State University (United States) are increasingly coming from more urban/suburban backgrounds; the same has been shared anecdotally among rangeland professionals recently and holds true for both undergraduate and graduate students. The authors further conclude that a student can have strong academic skills, but "if he/she cannot open the pasture gate, the knowledge may never be shared with the landowner" (Buckhouse and Powell 1985). It is not only practical skills that may be lacking in today's students, but lack of stakeholder involvement in rangeland curriculum development. For example, Taylor and Andrews (2012) describe a complete restructuring of rangeland graduate curriculum in Australia, which entailed a strategic approach that combined focus groups with stakeholders, course scoping workshops, and research on learning. The focus groups identified current and future issues and challenges; through the course scoping workshops, the authors detail that a significant outcome was "the learning and insights the scientists and academics gained about real-world contexts, local knowledge, and the emerging issues perceived by a wide range of stakeholders" (Taylor and Andrews 2012). This has led to increased awareness and ownership of the program by stakeholders, ultimately helping the program be recognized as "best practice" (Taylor and Andrews 2012).

Rangeland curriculum has a direct impact on the abilities of graduates entering the workforce. Thurow et al. (2007) surveyed Society of Range Management (SRM) members and undergraduate students at the University of Wyoming (United States) to investigate what aspects of rangeland curriculum were perceived as important. Within the top ten skills needed by professionals, an average score of 4.3 ± 0.8 (1 = grasp of general concepts to 5 = highly detailed proficiency) was given by survey respondents on public interaction (listening/collaboration/mediation skills), 4.0 ± 0.9 was given for technical writing, and 3.9 ± 0.9 was given for public speaking. Further, resource management (scientific application and techniques) and communication skills were listed as the top two things that respondents indicated a rangeland science program should provide to students. The authors conclude that employers that enact management objectives (e.g., state and federal land management agencies) are likely to be frustrated by the lack of focus on management and low proficiency in communication and quantitative skills (Thurow et al. 2007). Although this study addressed undergraduate students, collectively, we as range professionals who train students have not purposefully addressed these issues that arise in undergraduate rangeland curriculum and focus our research efforts – and therefore, the graduate education of our students – on fundamental (e.g., 'basic') research instead of emphasizing rangeland management and the proficiency of our students to communicate about it.

A Comprehensive Mentoring Framework For Rangeland Graduate Students

Using the knowledge gained from the existing research outlined above, we provide a comprehensive mentoring framework for rangeland graduate students that strives to address both the challenges between academia and outreach and the gaps in rangeland science curriculum. There are three mentorship components (MC) to the framework: MC1) addressing producer-driven problems, MC2) community-based outreach activities, and MC3) partnerships with local stakeholders (Fig. 1). The framework further outlines both *who* and *how* these components can be accomplished. Across all MC are graduate students, cross-pollinated researchers, and outreach specialists. Cross-pollinated researchers are those that cultivate a rich, inter-disciplinary "intellectual ecosystem." These researchers actively integrate ideas from other specialities to foster innovation and holistic approaches to rangeland management. An example would be a rangeland scientist who collaborates with an economist to evaluate the financial implications of sustainable grazing practices or with sociologists to understand the decision-making processes of producers during drought. Outreach specialists are trained and have the technical expertise in rangeland management, but also have a breadth of interpersonal skills such as relationship and capacity building, as well as the adaptability to tailor their educational approaches to different audiences. It is critical throughout the three steps of the framework that graduate students are trained by both cross-pollinated researchers and outreach specialists.

The focus of MC1 is constructing a strong foundation with producers. Researchers and outreach specialists can work collaboratively with graduate students to engage producers through several different avenues. One avenue would be to conduct focus groups and listening sessions with producers, with the purpose of understanding their perspectives on rangeland management and what challenges they face. Another avenue would be to conduct a formal needs-assessment to identify gaps between current states and desired outcomes, as well as to prioritize identified needs. Both methods will help promote knowledge exchange and the co-development of potential solutions, such as alternative grazing methods, that can then be researched. This not only helps facilitate trust, ownership, and collaboration with producers, but it demonstrates that their input is valued. A facilitator is likely to benefit these methods and can help remove the emotion that often surrounds critical rangeland management threats. Finally, integrated grants – grants that require outreach, in addition to research – are grants that provide several benefits. One, they are competitive and often have higher funding caps (e.g., $750,000 to several million USD) that will be viewed favourably by university administration. Two, because they require research *and* outreach to occur on the same project, there is ample opportunity to provide graduate students with training and experience in both aspects. Three, integrated grants typically allow for an interdisciplinary approach between researchers and outreach specialists, helping to underscore the importance of both to graduate students.

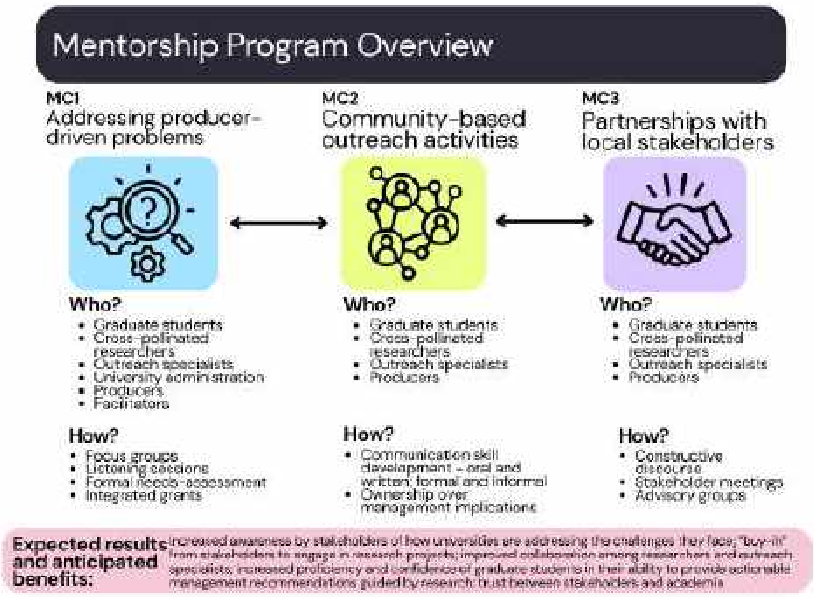

Figure 1. A mentorship program overview with three mentorship components (MC): MC1, addressing producer-driven problems; MC2, community-based outreach activities; and MC3, partnerships with local stakeholders. For each MC, a description of *who* and *how* is provided, along with overall expected results and anticipated benefits.

MC2, community-based outreach activities, provides mentorship for graduate students that is often disregarded. Outreach activities provide several informal opportunities for graduate students to develop their skills, particularly in both oral and written communication. This can be in addition to any formal (e.g., classroom-based) communication training that the university may offer. Graduate students can contribute to outreach activities and learn how to translate complex scientific concepts into accessible language for diverse audiences, through presentations and outreach articles for producers and the public. Another benefit of mentoring graduate students through outreach activities is that they will see the real-world application of their scientific knowledge, by helping to solve practical, producer-driven problems. Further, graduate students will feel empowered through participation and take ownership over the potential management recommendations suggested by their research. Finally, producers can also provide mentorship through these activities, by fostering relationships between academia and outreach, helping to expose students to diverse viewpoints and experiences.

The last piece of the mentorship program is MC3, partnerships with local stakeholders. This emphasizes and expands the groundwork that is laid in MC1 with producers. Specifically, MC3 helps graduate students enhance the success, relevance, and sustainability of their research. Partnerships further help graduate students learn the real-world application, as well as the social, cultural, and economic contexts of their research. These contexts often result in discourse that can be applied constructively and either developed into future research questions or used to create outreach programs that address stakeholder concerns. Some research projects – particularly those supported by integrated grants – benefit from an advisory group of stakeholders. By attending stakeholder meetings or leveraging an advisory group, graduate students can further develop their communication skills and help foster trust between academia and producers. Additionally, these interactions with stakeholders help graduate students increase career preparedness. By understanding the multi-faceted nature of rangeland management, students will be better prepared for interdisciplinary careers. Lastly, the involvement and familiarity with stakeholder groups explicitly demonstrates experience in applied research, outreach, and collaboration, thereby helping make students more competitive on the job market.

Implications

As outlined above, challenges exist between academia and outreach; these challenges can be overcome by mentoring the next generation of rangeland scientists to be 1) cognizant of the challenges, and 2) have the capacity to address them. We recommend that this is best achieved through mentorship of rangeland graduate students, via a three-component mentorship program that overcomes a common concern that the ivory tower of academia is "producing too much of the wrong kind of information" (McNie 2006). In addition to the benefits to graduate student training, the mentorship program we outline has several benefits for research/academia and stakeholders. Specifically, research quality may increase, as the increased collaboration with stakeholders ensures that research is aligned, and it may also improve access to local resources. Further, collaboration among researchers and outreach specialists will broaden perspectives on rangeland management, ultimately encouraging innovative and interdisciplinary approaches to problems. Stakeholders will gain access to emerging knowledge, ideally benefiting their operations. They will also benefit from the mutual learning that will co-occur with the academic insights the graduate students provide and the practical, hands-on knowledge they use daily. Overall, the mentorship program we outline has the potential to move the needle in rangeland graduate curriculum, bridging the gap between academia and outreach, while simultaneously fostering a new generation of leaders that are adept at collaborate, interdisciplinary, and impactful work.

Key words: art-based education; rangeland/grassland exhibits; valuing rangelands/grasslands

Abstract

Rangelands and grasslands are highly productive and valuable perennial-based ecosystems that provide a multitude of benefits for society. Yet they are highly threatened throughout the world which was the impetus for the UN designating 2026 as the International Year of Rangelands and Pastoralists. In North America alone, these ecosystems have contracted by 60-80% due to conversion to intensive agriculture, urbanization, power development, and other causes. While causes of loss vary, wide agreement exists that these biomes are undervalued by society despite their ecological, socio-cultural, and economic significance. This has led to increasingly urgent calls for wide-reaching education campaigns to raise awareness among the public and policymakers, and spur action to stop and reverse losses. In response, we look to the approach of Indigenous Peoples who have and continue to use art as a means of educating and are designing and deploying a pilot mass communication effort. Specifically, we aim to "go beyond the choir" and use "more than facts and figures" by developing 25+ creative, multi-media public exhibits to test the efficacy of arts-based education. We will use a mixed methods research design to evaluate the effectiveness of art in public settings (specifically variables of exhibit venue, media type, and messaging strategies) to increase awareness and knowledge, and drive behaviour change regarding support for rangelands and rangeland communities. We assembled a team of 30+ professionals across 12+ US western states and the Pacific Islands, Canada and Mexico who will help to recruit, design, and deploy content and exhibits. Content will be digitized and curated in collaboration with the Rangelands Partnership and key subject matter specialists including land stewards, Indigenous communities, rangeland scientists, Extension professionals, an evaluation researcher, and artistic directors. Outreach efforts are a key need identified by diverse groups working and living in rangelands and a clear guide for where limited resources will be most effective will be a critical factor in helping to preserve these lands.

Introduction

Rangelands (grasslands, shrublands, tundra, savannahs and woodlands) are threatened ecosystems around the world. Their services and relationships provide carbon sequestration, soil stabilization, water filtration, habitat, and human food. However, in North America alone, 60-80% have been converted to crops or non-agricultural use (Nature Conservancy Canada 2024, USFWS 2024, USGS 2023). While causes of loss vary, agreement exists that these biomes are undervalued by society despite ecological, socio-cultural, and economic significance (Bengtsson et al. 2019, Birdlife International 2024, Sayre et al. 2013). Rangelands have been mapped as "leftover areas" (Sayre et. al 2013), marginalizing their influence on public perception and land-use decisions.

Inadequate knowledge of rangelands has negative environmental, economic, and social consequences, including conversion (Lark 2020, Briske et al. 2024), desolated cultural landscapes (Rattling Hawk, Pers. comm.), and rural economic decline (Bardgett et al 2021). Consequently, producers and range professionals have called repeatedly for education going beyond the "choir" and using more than facts and figures. A promising avenue for the range-grassland community to explore that may prove effective is art-based education, which is known to provoke reflection and expand awareness through the 'affective' or emotional domain (Drumm et al. 2013, Lawrence 2008, Thompson et al. 2023). Indigenous Peoples have for many years utilized art as a means of sense-making, educating and documenting, creating dynamic and engaging expressions of knowledge and understanding (Sorenson 2013). At present, there is a lack of structured coalitions for mass communication to explain how different approaches may have different impacts across diverse populations (Devine et al. 2023, Lesen et al. 2016). As such, we have developed a coalition that seeks to explore the impacts of different art-based education approaches across diverse demographic populations. Our goals with this project are to:

1. Develop a western region network of 24 to 36 educational art exhibits to evaluate the effect of ecological context, city size, venue type, and exhibit openings on public comprehension of and engagement with critical rangeland and grassland issues.
    a. Evaluate the impact of art-based rangeland exhibits on public audiences not historically familiar with grass/rangelands by locating exhibit venues in non-rangeland ecological contexts and larger metro-urban areas.
    b. Evaluate our ability to reach new audiences with rangeland messages by partnering with and displaying arts-based educational content at novel exhibit locations such as airports, city halls, libraries, and shopping malls.
    c. Evaluate the impact of social gathering (i.e. public opening vs. no public opening) on level of engagement of attendees.

2. Investigate the potential for arts-based learning to enhance a sense of connection among Indigenous and non-Indigenous youth to their range/grassland landscapes
    a. Evaluate the effect of farm-based art-education workshops on comprehension of range/grassland topics among Indigenous and non-Indigenous youth.
    b. Evaluate the effect of classroom-based art-education workshops on comprehension of range/grassland topics among Indigenous and non-Indigenous youth.

Methods

This is a multi-year project with major portions of the effort being deployed in 2025 and 2026. Our first goal of developing a network, and then creating and disseminating educational art packets, is currently in progress. A network has been established with 24 confirmed venues and another 12 venues with conversations actively happening on logistics, including major venues like the Port of Seattle and the City of Los Angeles. We will continue to build on our network over the coming year and with installations put up in 2026. The educational art exhibit packets will contain 10-15 exhibit items (photography, mixed media, painting, etc) from around the world and we will start to compile materials for these in the beginning of 2025. We will develop a publicly accessible digital and physical library in collaboration with Rangelands Gateway consisting of at least 100 submissions of artistic audio-visual resources that are paired with one of ten priority messages about grass/rangeland issues in addition to the pre-composed exhibit packets. Exhibits will be installed in diverse venue types and at diverse geographic and demographic locations across the US, Canada and Mexico (Table 1) with active and passive surveys conducted at the different locations.

Table 1. General study framework for educational art exhibits.

Treatments (independent variables)	City size, venue type, ecological context, exhibit opening/no opening
Knowledge indicators	What rangelands/grasslands are; ecological, economic, and social importance; extent and decline; ecosystem services including habitat, C sequestration, biodiversity, water; services provided by producers
Attitude indicators	Expressed desire to learn more about grass/rangelands and increase support for producers, interest in meeting and purchasing from producers
Practice/behavior change indicators	Access information on policy, range issues; participation in community collaboration or association; purchasing intentions of grassland-based product; participation or facilitation of urban-rural cross-cultural exchange
	Speak out on behalf of rangelands; promote policy to include grasslands in climate response strategies;
Survey tools (passive)	QR codes on content, paper response questionnaires
Survey tools (active)	QR codes on content, participant observation, exit interview with venue host
Survey tools at case study sites	QR codes on content, participant observation, exit interview with venue host, intercept surveys, follow-up interviews with willing viewers

For our second goal, we will test two methods for educating youth about rangeland/grassland landscapes. The first method (a) is getting youth to the landscape (school-to-landscape), and the second is (b) taking the landscape to the youth (landscape-to-school). The first approach will utilize existing programs and programs in development where professionals host youth in a rangeland/grassland landscape and use art workshops (including photography, film, or other) to teach youth about the ecology, culture, and agriculture of the area. The second method is a less time and resource intensive endeavor wherein educational packets will be created for a multimedia experience about rangelands/grasslands that can be enjoyed in the classroom. This approach is tailored to the US primary and secondary education system to meet criteria required of teachers for science and art. While the experience will likely be less profound than actually going to a rangeland/grassland biome to learn about the ecosystem and the types of land uses that exist, we believe the opportunity to reach a larger population of youth is important. This approach will provide students with an opportunity to learn about rangelands/grasslands, while fitting within the time limitations of teachers and instructional requirements.

Results Thus Far

This project is currently in progress with the full deployment set to occur during the 2026 International Year of Rangelands and Pastoralists (IYRP). Efforts associated with the educational art exhibits are scheduled to begin in 2025 and while this effort is currently North America focused, we welcome the participation of our global rangeland communities. Material developed for this project will be made available on the Rangelands Gateway website (https://rangelandsgateway.org/). An overview of exhibit information and materials will be given in this presentation.

Program development for school-to-landscape events and material packet creation for landscape-to-school efforts are currently underway. In this presentation, we will be giving examples of how collaborators are developing school-to-landscape programs and we will be presenting examples of the landscape-to-school materials. These materials will also be available on the Rangelands Gateway website and the US based teachers-pay-teachers website (https://www.teacherspayteachers.com/). These materials are being designed with adaptive capacity in mind: people will have different needs in terms of art-based educational material and we want to create content that can be used broadly, with individuals having the opportunity to add their own local flair.

Discussion

The goal of this project is to provide diverse groups of people in rangelands/grasslands with ideas and materials to help educate people in non-rangeland areas and instil a sense of value and appreciation for the lands that many of us call home. While the direct impacts of efforts of this nature can be difficult to quantify, we know that talking amongst ourselves will not provide a solution to the current challenges that many of us face. As such, we need to reach beyond the choir and find diverse ways to reach diverse audiences. Findings from these studies will be shared through podcasts, extension products, webinars, conferences, manuscripts and partner networks. Our hope is to not just provide an outreach campaign for the 2026 IYRP, but reach beyond 2026 and create a culture of caring for rangelands into the future.

Acknowledgements

We are grateful to the many collaborators who are not listed here as co-authors, but who are participating in these efforts and providing critical perceptions to the development and distribution of materials. We also acknowledge the Western SARE granting organization for accepting our pre-proposed grant submission and await decision on the final grant submission.

Education and experience to empower the next generation of rangeland professionals

Launchbaugh, KL[1]; Hickman KR[2]; Johnson, PJ[3]; Edinger-Marshall, SB[4]

Key words: Career; University Degrees; Workforce Development; Youth Education

Abstract

The challenges facing rangelands and the human communities that rely on them are increasingly intense and variable. Management of the modern threats of damaging fire regimes, invasive plants, variable climates, and desertification of rangelands across the globe requires a skilled and knowledgeable workforce. Historically, most rangeland management professionals came from agricultural backgrounds, obtained a rangeland degree through educational programs that provided extensive hands-on field experiences, got real-world experience through internships or summer jobs, and/or received extensive training and mentoring through their employers.

Many emerging rangeland professionals today, however, come from urban backgrounds, often with little or no direct exposure to rangelands. Time constraints on established rangeland professionals, due to increased workload and limited personnel, result in less opportunity for emerging professionals to learn from experienced rangeland management trainers and mentors. A proposed emphasis on recruiting, embracing diversity, engaging modern educational practices, and fostering intentional mentoring is needed to empower emerging rangeland professionals to develop a full complement of important knowledge, skills, and leadership traits to successfully manage rangeland resources. The Society for Range Management is committed to supporting and promoting the full continuum of educating, training, and mentoring future rangeland management professionals. Programs include those targeting high school and college students as well as a new program for early career rangeland professionals called the Academy for Rangeland Career Success. While these efforts are largely focused on the United States, ideas and engagement are needed worldwide. Effective programs will be presented and opportunities to share ideas and successful approaches from across the globe will be highlighted to support the theme of valuing rangelands and pastoral systems for their societal contributions.

Introduction

Slightly more than a century ago, the discipline of rangeland science emerged with the primary goal of addressing the significant challenges associated with livestock production on grasslands, shrublands, and woodlands (Sayre et al. 2012). This development gave rise to the profession of rangeland management, which brought together scientists, government land administrators, and livestock producers in a collaborative effort. From the early stages of the profession, it was recognized that sustaining rangeland productivity and values depended on recruiting and educating skilled personnel to handle the complex challenges of rangeland management (Sampson 1954). To support this emerging profession, courses and academic programs were established at Colleges and Universities to train professionals able to manage grazing, fire, and invasive species, and thereby ensure the sustainability of rangelands worldwide (Abbott et al. 2012; Taylor et al. 2020).

Global challenges such as climate change, food security, water sustainability, energy production, biodiversity loss, and desertification are increasingly critical to society and pose significant threats to rangelands. Addressing these issues requires a robust and well-trained rangeland workforce, yet the persistent shortage of skilled professionals jeopardizes the health and sustainability of these ecosystems. The demand for rangeland professionals who possess both strong academic knowledge and practical experience has never been greater, underscoring the urgent need to cultivate and expand this essential workforce. To address this workforce shortage, we argue that those dedicated to sustaining rangeland health and productivity must: (i) identify and recruit a diverse group of rangeland professionals, (ii) transform rangeland training and education, (iii) mentor and support early career professionals, and (iv) foster networks of life-long learners.

Identify and Recruit Rangeland Professionals

Building a strong, well-educated rangeland workforce starts with recruiting individuals to pursue advanced degrees essential for a career in rangeland management. One of the primary reasons prospective students do not choose degrees in rangeland ecology and management (REM) is simply a lack of awareness that such programs exist (Abbott et al. 2012). When exploring degree options through university websites, which often feature hundreds of majors, degrees, and certificates, students are unlikely to come across REM programs unless they are already familiar with the profession. Students may be more likely to encounter REM degree options if they are bundled with broadly recognized fields such as wildlife management, forestry, or environmental science. On-campus recruitment efforts, such as visits by rangeland faculty or students to introductory courses in biology, botany, or chemistry, or presentations to freshman interest groups, have proven effective in raising awareness. Additionally, exposure to the profession through youth range camps, interactions with rangeland professionals, or guidance from parents, teachers, or high school counsellors also play an important in influencing students to choose an REM major. Anecdotal evidence from reviews of several REM programs accredited by the Society for Range Management (SRM), suggest that university Range Club tabling and peer-group ambassador programs are an effective way to recruit students to REM programs. These outreach efforts are critical for attracting the next generation of rangeland professionals.

In 2020, a survey conducted for the Range Science Education Council (RSEC) explored rangeland degree choices at U.S. colleges and universities. Male and female students were nearly equally represented among the 228 respondents and about 75% of respondents were range majors. The survey revealed that 43% of range majors across the western U.S. initially enrolled as REM majors, while 57% switched to the REM major later. Among those who changed majors, 66% did so before taking a range course, while 37% switched after taking one. The top three reasons for changing to an REM major were perceived career opportunities (72%), the uniqueness of the major (40%), and the potential work locations (46%). The survey also showed that about 60% of REM majors entered as freshmen, while 40% were transfer students. These students came from various backgrounds: very rural areas (26%), towns with populations between 2,500 and 25,000 (38%), cities with populations over 25,000 (30%), and other locations (6%).

When asked how colleges and universities could increase enrollment in range-related majors, 87 respondents provided suggestions. The majority (78%) emphasized the importance of outreach to communities, schools, and other students, while fewer respondents mentioned the need for curricular or programmatic changes (29%) and highlighting employment opportunities (25%). Universities need to sharpen and expand their recruiting efforts as the demand for rangeland graduates continues to be high. In the U.S., 124 students per year graduated with an undergraduate degree in REM between 2011 and 2022 (Educational Digest, Tables 318.30) and the average demand for Conservation Scientists (of which range management is a part) is projected at 140 per year between 2023 and 2033 (U.S. Bureau of Labor Statistics Occupational Outlook Handbook).

Programs aimed at deepening and diversifying the rangeland workforce should also consider avenues to attract and support non-traditional students seeking REM degrees. Developing 2-year technical programs and building relationships with faculty in community colleges could increase the number of students seeking rangeland degrees and provide options that are more affordable to a wider array of students (Bullard 2024).

Transform Rangeland Education

Rangeland education is predominantly delivered through traditional, on-campus classes led by university faculty. Over recent decades, the reduction in faculty with specialized expertise in rangeland science, coupled with a growing emphasis on research over teaching, has significantly diminished the coverage of rangeland topics in many academic programs. This decline comes at a time when the demand for graduates in REM is increasing. Furthermore, many prospective students are geographically constrained, limiting their ability to access the traditional coursework essential for career advancement. To address these challenges, it is imperative to modernize rangeland curricula and adopt innovative instructional methods that broaden access, support student participation, and enhance professional development opportunities.

Advances in communication technologies over the past 25 years have created significant opportunities to serve place-bound students, enhance teaching resources for educators, and facilitate collaboration across universities and continents. Currently, several asynchronous web-based courses provide rangeland education to students. However, effective rangeland management requires strong skills in social interaction and the ability to engage stakeholders with local knowledge and solutions (Sampson 1954; Roche et al. 2021; Taylor et al. 2024). To address this need, distance-accessible courses could incorporate structured discussions involving topic experts or practitioners with deep local knowledge. Students might be tasked with investigating livestock operations, ecological challenges, wildlife habitat programs, or rangeland improvements in their communities, sharing findings with their peers. Laboratory activities could be designed to have students collect specimens or data, analyse results, and present their findings collaboratively. Professors could also collaborate to create innovative assignments and documentary-quality class presentations, moving beyond reliance on outdated or inconsistently prepared notes and presentations.

To better prepare the next generation of rangeland managers, it is essential to explore innovative approaches to course delivery. For instance, distance-accessible postgraduate programs have been designed to offer flexible educational pathways, enabling students to progress from graduate certificates to master's degrees (Ferguson 2021). Another promising approach is the use of workshop-style courses, such as those offered at the University of Nevada-Reno, which combine online learning with intensive field workshops to provide hands-on, practical knowledge. Additionally, workshops and courses could be developed to serve both degree-seeking students and professionals pursuing continuing education, fostering an inclusive learning environment that meets diverse educational and needs for career advancement.

Support Early Career Professionals

Offering early-career rangeland employees support and professional development is crucial after recruiting and training individuals for careers in rangeland ecology and management. In 2010, the U.S. Bureau of Land Management published a "white paper" highlighting concerns about the agency's shortcomings in providing adequate training, mentoring, and onboarding for early-career rangeland management specialists. The paper identified widespread issues with retaining early-career employees and ensuring they could effectively serve both the rangeland resource and its stakeholders across various offices and regions. It warned that without meaningful development strategies for new employees, these challenges would worsen. Fifteen years later, those predictions have materialized. At the 2023 International SRM Meeting more than 20 employers, including agency representatives and private non-government organizations, confirmed that these issues remain pervasive.

Several factors contribute to the challenges facing rangeland professionals today, including shifts in their backgrounds, changes in academic preparation, and limited training and onboarding by employers. Historically, many rangeland professionals came from agricultural backgrounds, completed rangeland degree programs with extensive hands-on field experiences, gained real-world exposure through internships or summer jobs, and received comprehensive training and mentoring from employers. In contrast, many emerging professionals now come from urban backgrounds with little to no direct exposure to rangeland management. Hands-on field experiences are increasingly limited, even in high quality REM programs, and fewer professionals gain practical experience through internships or summer jobs. Additionally, time constraints on established professionals, caused by heavier workloads and staffing shortages, reduce opportunities for mentorship. To ensure effective rangeland management and retention of employees in the field, it is vital for emerging professionals to develop essential knowledge, skills, and leadership traits.

The Society for Range Management created the Academy for Rangeland Career Success (ARCS) to address the professional development needs of early-career rangeland management professionals. ARCS aims to enhance participants' knowledge, skills, and leadership in four key areas: Professionalism, Working with People, Understanding Cultures, and Subject Competency. Over the course of a year, participants engage with experts through a combination of remote and in-person mentoring and training. The curriculum focuses on addressing skill gaps, strengthening existing competencies, and leveraging individual strengths for mentoring others. While ARCS has shown promising results in its first year, agencies and employers must also invest in programs to ensure the retention and success of early-career professionals.

Foster Networks of Life-Long Learners

An essential strategy for supporting the future of rangeland management is fostering networks of lifelong learners. Building strong connections among land managers, ranchers, scientists, extension educators, and conservationists is critical to addressing the challenges facing rangelands today. Diversifying the rangeland workforce is also key to attracting new professionals and equipping them with the tools needed to succeed. This diversification should encompass various stages of career development, creating an inclusive environment for continuous learning and innovation (Taylor et al. 2020).

To achieve this, the Society for Range Management has established programs and initiatives that emphasize professional development throughout career stages. SRM's network spans from high school youth programs to collegiate students participating in the Student Conclave, and from early-career graduates in the Young Professionals Conclave (YPC) and the Academy for Rangeland Career Success, to mid-career and seasoned professionals. These networks not only help individuals transition through different career phases but also foster a culture where professional development is recognized as a critical component of career growth. However, there is evidence that we need to reach more rangeland professionals to help them develop the mindset that professional development is key for their continued career progression.

Members of the YPC and ARCS program benefit from targeted mentoring and networking opportunities, helping them build connections with other rangeland professionals within the SRM As they transition to regular membership, their continued professional growth depends largely on self-motivation to engage with peers and actively contribute to the profession. At every stage, SRM focuses on fostering a passion for rangelands and enhancing members' technical skills by introducing emerging tools like drones and artificial intelligence (AI).

Professional development opportunities are not limited to SRM annual meetings and section gatherings, which provide forums for research dissemination, extension updates, and producer engagement. The importance of lifelong learning in rangeland management extends globally, as evidenced by the Australian Rangeland Society (ARS), which has played a central role in professional development both within Australia and internationally (Taylor, et al. 2020). Such efforts highlight the value of continuous skill enhancement and the critical role these opportunities play in developing leaders within the rangeland profession.

By fostering a robust network of lifelong learners and emphasizing professional development, SRM, ARS and other rangeland organizations ensure that rangeland professionals remain equipped to address evolving challenges and lead the way in sustainable land management.

Conclusions/Implications

It is urgent to provide educational opportunities for students of REM and support for career professionals to succeed and excel in the management of rangelands as rangelands face unprecedented challenges to their ecological resilience and the human communities they sustain. The future of rangelands lies in the hands of the next generation. Our commitment to fostering and supporting these students and early-career professionals will either pave the way for or hinder the sustainable management of rangelands across the globe.

Utah range camp: helping youth value rangelands

Farnsworth, C[1]; Greenalgh, L[2]; Longmore, A[3]; Esplin, B[4]

[1] Utah State University Extension Grand County; [2] Utah State University Extension Tooele County, [3] Utah State University Extension Box Elder County, [4] Utah State University Extension Iron County

Key words: Rangeland; Youth; Education; Camp; Management

Abstract

In Utah, there are nearly 45 million acres of grazing land; 73 percent federally owned, 9 percent state owned, and 18 percent privately owned (GOPB, 2011 as cited in UDAF 2019). Rural economies benefit from livestock grazing on these rangelands, many of which are managed for multiple uses including recreation, mineral extraction, timber harvest and other practices. Political and public sentiment toward livestock grazing on public lands is becoming less positive as the attention turns from livestock and conservation to recreation and preservation. In 1973 Utah State University and the Utah Society for Range Management started Utah's Range Camp for high school youth in an effort to help the rising generation see the value of rangelands and livestock grazing. Up to 25 high school youth are allowed to participate in this program each year. The camp teaches youth about the basics of rangelands and natural resources. Youth learn about poisonous plants, noxious weeds, wildlife, livestock, and how to identify plants. If possible, the camp is changed to a different location each year to give returning youth new perspectives. Youth experience each ecosystem available in the area from desert shrubland to alpine tall forb communities. Professors, agency land managers, and ranchers are brought together to share with the youth about their jobs and different issues they face in their careers and ways to manage rangelands. Many young adults come to camp because they want to work in a range related field or because their family is involved in range, while others come because it gives them an edge at FFA (Future Farmers of America) competitions. Some attendees may never be involved in a range related career, but they are taught the importance of natural resources and multiple uses and become vital to the future of rangelands as educated community members.

Introduction

In 1954, the Utah Section of the Society for Range Management (Utah SRM) decided to begin holding youth Range Camps to speed up the adoption of rangeland management practices and principles among Utah ranchers (Smith, 1981). Range Camp is still used to help the public adopt rangeland principles but it is also used to help the students to network, expose them to potential colleges and careers and succeed in FFA competitions. The first camps were held from 1958-1962 and, starting in 1973, have been held annually ever since. While attendance has not been accurately counted prior to 2016, an average of 20 individuals attend each year making an estimated total of 1,100 youth that have participated in the Utah Range Camp since its start.

Methods

Originally, when Range Camp began, it was the responsibility of the Utah State University Rangeland Extension Specialist to direct the camp. This has evolved over time, the only real consistency being that the Range Camp Director was a member of the Utah SRM and was chosen by the previous Camp Director.

Each summer, up to 25 Utah High School youth between the ages of 14 and 18 who are interested in Rangeland Management and Natural Resources apply to attend Range Camp. Camp is usually held for one week (Monday-Thursday) in the summer, when most plants have finished their growing cycle. A site is chosen to base the camp out of for the entire week. Each year, it is the intent to change the location of the camp to give repeat students the chance to experience different areas. Depending on the venue, young women sleep in a cabin and young men camp in tents. Usually there are bathroom and kitchen facilities provided. Leaders for the camp are invited by the Camp Director and include Range Specialists from Federal and State Agencies, Universities and institutions, and the private sector.

Throughout the week, students learn about, collect, press, and correctly label 20 plants on their plant list. They are graded off of neatness and accuracy. Plant ID tests are held at several locations each day in which the student must properly identify the plants common name, growth form (grass, forb, woody), life span (annual, perennial), origin (native, introduced), forage value (desirable or undesirable for grazers and browsers), and whether the plan is toxic. Students should take notes and complete worksheets to receive full credit for participation. Worksheets include; forage production estimation, line point intercept, line intercept for shrubs, soil stability, and grazing utilization. These are filled out while a professional helps them complete these hands-on monitoring activities. At the end of the week each student must give a prepared two-minute oral presentation on something they learned at camp. Students are judged and graded and the combined winner and runner up are chosen to represent the Utah SRM by competing at the High School Youth Forum at the National SRM Meeting. The winners are given financial aid by the SRM to attend. To maintain high standards, students who do not achieve 50% or greater are not welcomed back to attend camp the next year. Previous winners may attend the next year but will not compete.

After attendees are checked in, they are given a plant press, a grass and forb identification field guide, water bottle, swag bag provided by a sponsoring college, pencil and pen, and a camp binder. The binder contains; the camp agenda, the Western National FFA Range CDE practice worksheets, ideas for a career in rangelands, instructions for writing an effective resume, the Western Rangeland Career Development Event Manual, several Ecological Site Descriptions that match locations the group will visit during camp, and several plant ID test sheets and rangeland monitoring forms. The first day is spent giving lectures and trainings on Introductions to Rangelands, Plant Identification, and Soils.

Each day begins with showers and breakfast and then the group travels to a range location using vans. Each day focuses on a different zone. The group is able to familiarize themselves with the low brush desert, semi desert, foothills, mountain brush, mountain grasslands, and alpine tall forb zones anywhere from 2000 to 11,000 feet in elevation throughout the week. Rangeland principles are discussed, monitoring is practiced, plants collected, and students are tested on plants in each zone. Students are able to learn from local land managers about current issues and practices and ask questions about their jobs. Time is taken to discuss toxic plants, noxious weeds, soil texture, aspect, climate, precipitation, vegetation, wildlife, and livestock in each zone.

Each evening is spent with dinner and more lectures and trainings in a classroom setting. Lectures are usually given by a representative of a college or range related career detailing their jobs or research. Other topics include discussions on livestock stocking rates, wildlife conflicts, noxious weeds, toxic plants and innovations in rangelands such as virtual fencing. Evenings are finished up with the students preparing for their oral presentations and labelling and pressing plants collected that day. At the end of the week, winners are selected and camp is cleaned up.

Results

To show the long-term impacts of Range Camp, a survey was created and sent out to all previous students on file, and distributed to members of the Utah SRM and State and Federal land management agencies within Utah. The 49 survey respondents previously attended Range Camp as a youth. 100% responded that it was important that youth attend Range Camp and would recommend that other youth attend. Respondents noted that it is a great way to teach the rising generation the importance of rangelands, it prepares youth to participate in FFA Contests, prepares youth for employment, and it is a great networking tool to introduce students to colleges and career paths. Those who attended Range Camp noted that they loved gaining knowledge of rangelands and the friendships they built through the program. 58% of the attendees attended the camp more than once. Those who only attended the camp one year noted that they would've attended more than once had they been able to. The top two reasons for not attending the camp a second time was that the students had either aged out or their Agriculture Teachers did not notify them of the activity. Figure 1 shows which years the survey participants attended Range Camp. Figure 2 shows the reasons youth attended Range Camp.

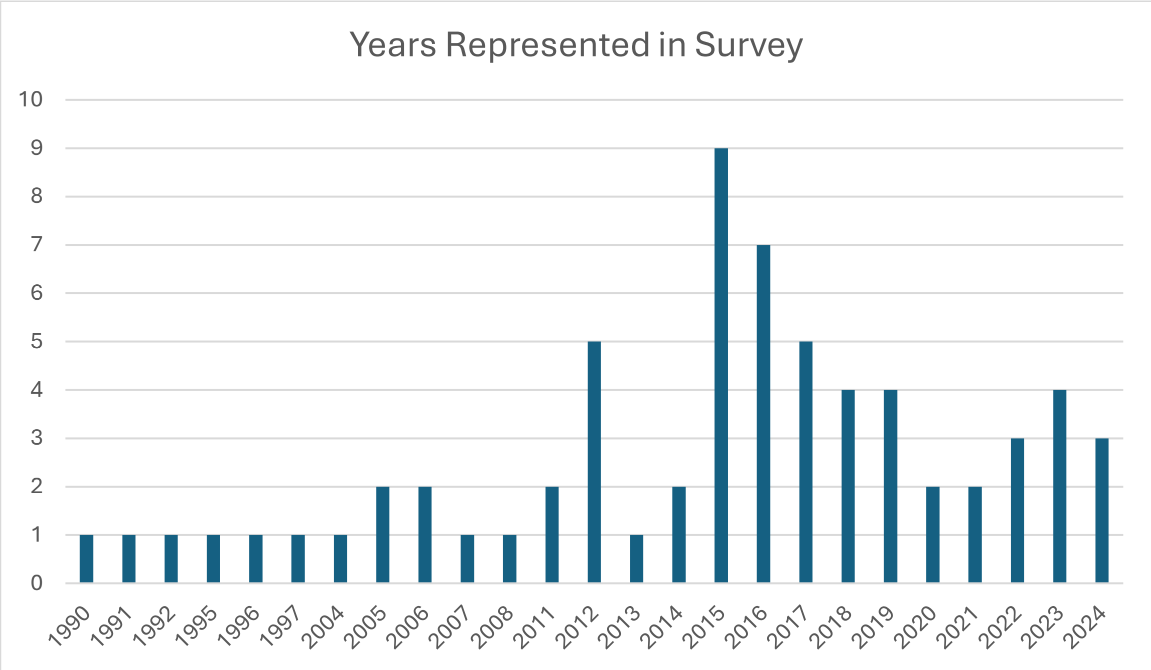

Figure 1

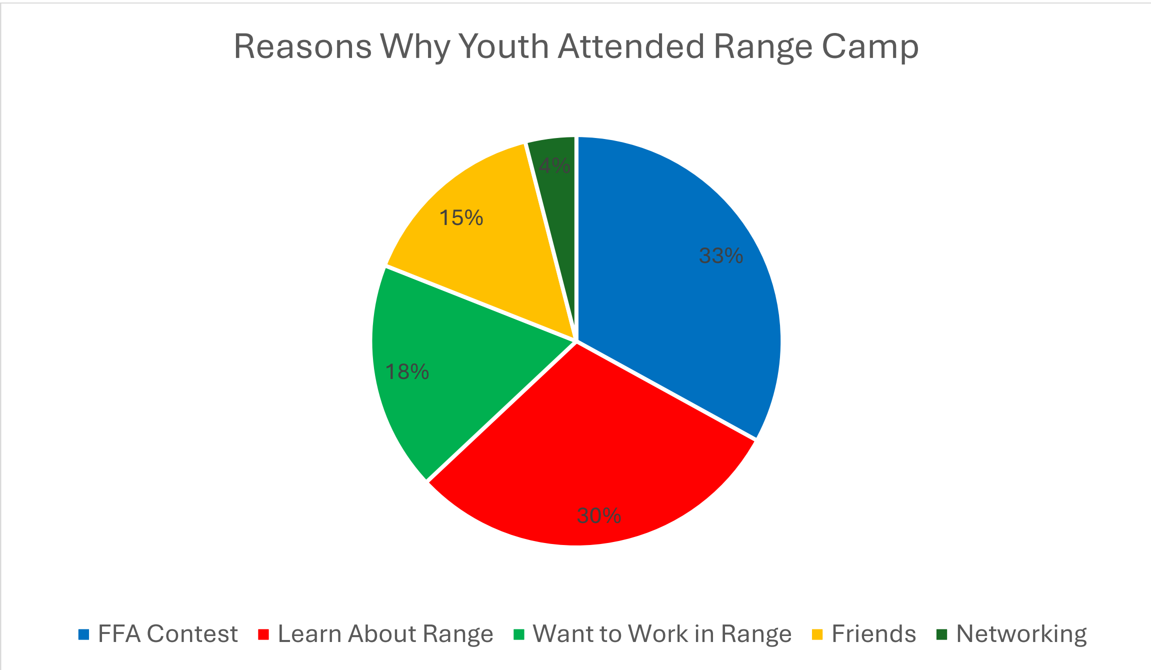

Figure 2

All survey participants rated the quality of the instruction and quality of the instructors as very good or excellent. 54% of youth said that Range Camp influenced their decision to pursue a college degree in Rangeland or Natural Resources and 56% said that it influenced which university they chose to attend. Utah State University, Southern Utah University, and Snow College were the higher institutions that Range Camp Participants attended. 39% of respondents said that they applied for a range related internship because of Range Camp. 83% of those who completed a range internship went on to work in a range related field and 73% responded that range camp influenced who they chose to work for. The employers listed are the United States Department of Agriculture, Bureau of Land Management, United States Forest Service, National Park Service, Natural Resource Conservation Service, and private ranches. 100% of those working in a range related career noted that Range Camp helped them be a better rancher or range manager. 100% of survey participants responded that Range Camp has positively influenced their current career choice and has helped them to positively contribute to society and the rising generation. All survey participants noted that they still use knowledge gained from Range Camp.

Discussion

Only an estimated 5% of Range Camp attendees completed the survey. Until 2016, data was not collected from the participants and the majority of the attendees contact information listed were school emails that became invalid after the students graduated. Most of the results were gathered by locating previous attendees via Facebook Messenger. Some survey applicants were reached through the Utah SRM email list serve, however, this would only reach individuals that are currently involved in rangeland management within the state of Utah. Moving forward, camp participants will be asked to fill out contact information using their personal emails in hopes to gain more long-term data on the camp. Although part of Range Camp is to help students do better on FFA competitions, very little information is had as to whether Range Camp has consistently helped with this goal. At the 2024 Utah Range FFA Competition, seven of the top ten individual winners and 5 of the top ten teams participated in Range Camp. At the 2024 Western National FFA Competition, one of the top ten individuals and one of the top ten teams attended Range Camp. These results will be followed more closely in the future. Range Camp has proven to be an important recruitment tool for colleges and employers. Only the employers and colleges that frequently send a representative to Range Camp benefit from recruiting these students. This information will be used to help increase participation from other employers and higher institutions. Another key note is that those students who pursued a range related internship clearly had more success in obtaining a career in range management, this underlines the importance of internships. In conclusion, Range Camp has successfully aided students in pursuing higher education and range related careers and has positively represented range management practices to individuals not involved with rangelands.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Drylands Summer School: a pathway from training to a community of professionals

Valenzi, V[1]; Herrera, PM[1]; Hofer, T[1]; Rezende, M[1]; Gerbaldo, L[1]

[1] FAO, Forestry Division

Key words: drylands; school; monitoring; agrosilvopastoralism; global

Abstract

Forests and agrosilvopastoral systems in drylands contribute to landscape resilience and environmental sustainability. They support species adapted to harsh ecological conditions and provide essential goods and ecosystem services, as well as enhanced resilience for dryland communities. When sustainably managed, they can alleviate poverty, ensure food security and improve livelihoods worldwide.

Drylands and rangelands are home to over 2 billion people globally but face significant challenges, including land conversion, climate change, unsustainable practices and poorly designed restoration programmes. The Food and Agriculture Organization of the United Nations (FAO) Drylands Programme, under the mandate of the Committee on Forestry Working Group on Dryland Forests and Agrosilvopastoral Systems (COFO WG), addresses these challenges by promoting good practices for the sustainable management, protection and restoration of drylands.

The only subsidiary body of the Committee on Forestry working specifically on dryland forests, the COFO WG is fostering resilient dryland ecosystems by training experts to drive transformative policymaking and management through its Drylands Summer School initiative, which builds a global community of practice through its participatory training programmes.

The Dryland School initiative explores transformative approaches to building climate-resilient dryland systems. The inaugural Drylands Summer School, held in Amman, Jordan, in 2023, equipped 22 participants from diverse dryland regions with tools to enhance resilience, focusing on context-specific solutions and monitoring progress through cross-cutting indicators. The second edition, hosted at the CIFOR-ICRAF (Center for International Forestry Research and World Agroforestry) Campus in Nairobi, Kenya, on 12–15 September 2024, expanded this effort with an enriched curriculum and a field trip to showcase practical applications of monitoring drylands and agrosilvopastoral systems towards climate change and sustainability.

Introduction

The Dryland School series addresses the critical need for transformative management of drylands. Currently, the dry areas of our planet are becoming increasingly vulnerable to climate change and unsustainable practices, leading to decreased production and land degradation. By training experts to drive policy, management and restoration shifts, the initiative fosters a shared vision for resilient dryland systems.

The Second Drylands School, titled “Monitoring Restoration in Agrosilvopastoral Systems for Sustainability and Ecosystem Services”, aimed to enhance participants' capacities to monitor, evaluate and provide feedback on sustainable dryland management practices. Its specific objectives were to: (1) deepen understanding of challenges and participatory approaches in managing dryland agrosilvopastoral systems; (2) adapt and apply monitoring frameworks for sustainable management and restoration; (3) co-define indicators with local stakeholders and gather field data; and (4) promote knowledge exchange and establish a long-term community of practice.

Methods

The Second Drylands School was a dynamic four-day programme, held on 12–15 September 2024 at the CIFOR-ICRAF Campus in Nairobi, Kenya. It included a one-day field trip and was facilitated by a dedicated CIFOR-ICRAF team with technical support from FAO and partner organisations. Emphasising experiential learning, the course placed participants’ knowledge and experiences at the core of the curriculum, following a well-structured “storyline” to ensure logical progression and continuity.

As part of the selection process, participants submitted case studies of their work, which were further developed during the course. Participants were also required to complete FAO's e-learning course on dryland forests and agrosilvopastoral systems. The curriculum blended theoretical knowledge with practical, hands-on activities, incorporating diverse formats such as technical lectures, group discussions, individual exercises, peer-to-peer learning and outdoor activities. This variety created an engaging and interactive environment, with the programme’s technical focus fostering in-depth and productive discussions.

The programme comprised seven dedicated sessions led by experts, addressing critical issues in dryland monitoring and management. These included monitoring frameworks, tools and approaches, design and implementation of indicators, and adapting monitoring strategies to pastoralist communities. The first day introduced the principles of monitoring drylands, during which participants shared their individual case studies and action plans. The second day focused on sustainability indicators and frameworks, with participants working in groups to refine their plans.

The third day featured a field trip led by the Kenya Forestry Research Institute’s (KEFRI) Dryland Eco-Regional Research Centre in Kitui. Participants visited the KEFRI Tiva Woodland Conservation site to learn about dryland restoration technologies, a commercial forest farmer in Kabati, and the Kyawean Community Forest Association’s restoration efforts in the Kyawea Forest Landscape. This hands-on experience highlighted practical application of dryland monitoring and restoration techniques.

On the final day, the programme explored scaling-up monitoring from local site-level efforts to global surveillance, featuring citizen data-collection practices. Participants shared their refined action plans and visions during group sessions, culminating in a discussion of future opportunities, such as the International Year of Rangelands and Pastoralists (IYRP2026), the upcoming International Rangeland Congress in Adelaide, Australia, and the third edition of the Drylands School.

The Second Drylands School was strategically scheduled before the Global Landscapes Forum (GLF) Africa event on 17 September 2024 at the CIFOR-ICRAF campus. During GLF Africa, the FAO team presented the outcomes of the Drylands School, showcasing its success.

The course fostered a positive and collaborative atmosphere, encouraging innovative and forward-looking discussions. Participants from diverse institutional affiliations and professional backgrounds actively shared experiences, enriching discussions and fostering mutual learning. Structured sessions enabled critical reflection on personal projects, promoting the enhancement of participatory monitoring practices.

Networking and experience-sharing were central to the programme, with participants exchanging insights and receiving peer feedback. These efforts aimed to build a global community of practice in dryland restoration, supported by the adaptation of established participatory monitoring and evaluation (M&E) protocols. By equipping participants with actionable tools and methodologies, the Drylands School strengthened their capacity to address the complex challenges of dryland restoration and management.

The Second Drylands School itself followed an M&E procedure led by the organisers and supported by a daily session of recap and reflection, with a final evaluation session completed by means of an online survey sent after the school ended. The evaluation survey was structured into five categories: ‘Global item’, ‘Organization’, ‘Methodology and program’, ‘People’ and ‘Logistics’ (see Figure 1).

Results

The Second Drylands School marked a significant milestone in a larger, long-term initiative to foster transformative dryland management. Participants developed personal action plans during the course, tailored to apply the knowledge and skills gained, and were encouraged to implement these plans in their work. The programme emphasised sustaining momentum by encouraging participants to apply their learnings actively and to champion dryland restoration efforts.

The results of the evaluation survey show how the participants considered the Drylands School to have been a memorable and fruitful experience. The organisation and efforts to make the stay enjoyable were highly appreciated. The event was rated as well organised, and the attendees appreciated the selection of participants based on diversity of backgrounds and experiences, which allowed deep exchange in the sessions and networking. Participants expressed pride and satisfaction, noting improvements in their project management skills and understanding. Figure 1 summarises the results.

Figure 1. Results of the evaluation survey, based on answers by 19 participants

To support continued engagement, plans are underway to establish an alumni network, linking participants in the second Drylands School with those in the inaugural one. This network aims to foster ongoing collaboration, knowledge sharing and professional growth. Participants were also encouraged to leverage their participation in the Drylands School to enhance their professional profiles and advocate for improved dryland management practices globally.

Discussion and conclusions

The 2024 Drylands School highlighted the complexity of dryland ecosystems and emphasised the importance of a landscape approach that integrates both physical and socio-economic dimensions of resource management. Effective dryland management requires consideration of diverse factors, including plants, soil, water, tenure security, livestock and economic dynamics, with careful negotiation of trade-offs between production and conservation.

A focus on monitoring emerged as a critical yet complex component of sustainable management. Participants were introduced to a wide array of tools, methodologies and communities of practice spanning local to global levels. The selection of appropriate monitoring tools depends on the specific challenges being addressed and the geographic scale of application. Participatory monitoring was particularly emphasised for its role in fostering ownership and ensuring relevance. Developing SMART (Specific, Measurable, Achievable, Relevant, Timely) indicators remains a challenge, particularly for integrating indigenous knowledge, which often informs local decision-making and management practices. Transparent organisation of data and information was underscored as essential for effective monitoring.

Field observations, validation and verification were identified as integral to successful monitoring efforts, alongside the involvement of local communities to ensure ownership, validate findings and align priorities with local needs. The course also underscored the need for combining top-down and bottom-up approaches to dryland management, ensuring that national and provincial policies are informed by field realities and that grassroots initiatives are scalable within policy frameworks.

The deliberations emphasised that addressing livelihood aspects of sustainable dryland management is often more complex than managing physical components. However, building on lessons learnt and success stories offers significant opportunities for progress. Ultimately, achieving resilient and sustainable dryland ecosystems requires an integrated, participatory and adaptive approach that bridges local realities with broader policy frameworks.

Acknowledgements
The Second Drylands Summer School was held in partnership with the United Nations Convention to Combat Desertification's (UNCCD) G20 Global Land Initiative, CIFOR-ICRAF, the World Overview of Conservation Approaches and Technologies (WOCAT) whose Secretariat is hosted by the Centre for Development and Environment (CDE) of the University of Bern, the Swedish University of Agricultural Sciences (SLU), the Agricultural Research Council of South Africa (ARC-LNR), the International Year of Rangelands and Pastoralists (IYRP2026), the Community Jameel and Jameel Observatory, the GEF-7 Sustainable Forest Management Impact Program on Dryland Sustainable Landscapes (DSL-IP) and the Kenya Forest Service.

As well as being a partner, the UNCCD G20 Global Land Initiative was the main sponsor of the Drylands School, and the Community Jameel funded the field trip.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Color country natural resource camp – teaching high school students about natural resource career opportunities

Scow, B [1]; Cox, S [1]; Frey, N [1]; Parent, V [1]

[1] Utah State University Extension, Utah, United States

Keywords: Natural Resources, camp, career, outdoors

Abstract

The overarching goal of Color Country Natural Resource Camp (CCNRC) is to give participants an opportunity to learn, in a hands-on environment, about career paths in the natural resource field. At the five-day camp, participants spend four hours every day in "Investigations" over the period of five days, these investigations facilitate learning about the areas of vegetation, soils, land use, aquatics, and wildlife with an instructor who works in these fields. This camp has been evaluated every year, with results showing positive youth development in all the investigation areas with a greater appreciation for recreational activities. In 2024, participants were evaluated on their intent to pursue a natural resource career and revealed significant increases in campers' understanding of natural resource topics and familiarity with career paths in the field. However, there was no significant change in immediate career interests, with the exception of increased interest in soil-related careers.

Introduction

CCNRC was created in 1993 and currently just completed its 31st year. This camp is managed by Utah State University (USU) Extension in partnership with the Utah Division of Natural Resources, Red Cliffs Desert Reserve, local Bureau of Land Management and Forest Service representatives, and other specialists at USU Extension from around the state of Utah. The purpose of this camp is to help participants explore career fields in natural resources in the areas of land use, aquatics, wildlife, soil, archaeology, soil, and vegetation. Currently in the United States, these careers are not taught or highlighted in our high schools (secondary schools). The National Science Board (2014) noted that the number of college students enrolled in the sciences has been steadily declining since 2010. Conversely, the demand for more scientists and experts in natural resources, particularly renewable energy, continues to grow (Frey and Parent 2019). From our work in other fields and youth camps, we know that youth's interest in a subject matter often improves once they have hands-on opportunities in those areas. CCNRC also educates participants on outdoor recreation opportunities, depending on the year and location, can include archery, rifle shooting, horseback riding, rock climbing, rappelling, hiking, wilderness survival, mountain biking, and orienteering. This camp hosts up to 35 high school-aged youth and is held at one of three remote campsites for five days each year.

The objectives of the program, starting in 2024 are:

1. Evaluating changes in participants' knowledge of natural resources before and after attending the camp.

2. Measuring the level of interest in natural resource-related higher education and careers among campers.
3. Determining the influence of camp experiences on career and educational decisions.

Methods
To evaluate the camp's effectiveness, we implemented a Pre- and Post-Camp Survey Design. Surveys were administered at two points: (1) before the camp began (pre-camp survey) to establish a baseline and (2) after completing all camp activities (post-camp survey) to assess changes in knowledge, interest, and career aspirations.

The **Pre-Camp Survey** measured participants' initial understanding, interests, and aspirations in natural resources using a Likert scale to gauge agreement with key statements. The **Post-Camp Survey** mirrored this structure, enabling direct comparisons to identify shifts in attitudes and knowledge.

Both surveys combined quantitative and qualitative methods. The Likert scale responses provided measurable data, while open-ended questions captured deeper insights into participants' interests and experiences. Example questions included: *"What specific natural resource fields interest you?"* and *"What did you hope to gain from the camp experience?"*

Data analysis involved descriptive statistics (means, standard deviations) and inferential statistical tests (p-values) to determine significant changes over time. A **95% confidence interval** was used to assess statistical significance. Qualitative responses underwent thematic analysis to identify recurring themes in participants' interests and career aspirations.

The study aimed to determine whether the camp significantly influenced participants' understanding of natural resource topics, interest in higher education, and career aspirations. Survey questions were categorized into three areas: **(1) Personal Statements, (2) Subject Understanding, and (3) Interest in Natural Resource Careers.**

Results
Personal Statements The interest in pursuing higher education showed a slight increase from a pre-camp mean of 3.83 to a post-camp mean of 4.04, with a mean difference of 0.21. However, this change was not statistically significant (p-value: 0.4264), suggesting that the camp did not substantially impact this aspect. Similarly, the interest in a career in natural resources increased marginally from a pre-camp mean of 3.50 to a post-camp mean of 3.57, with a mean difference of 0.07, and this change was also not statistically significant (p-value: 0.77). In contrast, there was a significant increase in familiarity with career paths in natural resources, from a pre-camp mean of 3.46 to a post-camp mean of 4.13, with a mean difference of 0.67 and a p-value of 0.014. This indicates that the camp effectively enhanced campers' awareness and understanding of career opportunities in this field.

Qualitative Data Analysis
Summary of Pre- and Post-Survey Results To assess the impact of the camp on participants' knowledge and interest in natural resources, we compared pre- and post-survey responses. Statistical significance was determined using a **p-value threshold of 0.05**, indicating meaningful changes in participants' understanding and interests. (See Table 1).

Key Findings: Several areas showed statistically significant increases in knowledge:

- Familiarity with career paths in natural resources ($p = 0.0139$)
- Environmental science ($p = 0.0074$)

- Natural resource conservation principles (*p* = 2.201E-05)
- Outdoor recreation management (*p* = 0.0041)
- Soil (*p* = 0.0306)

Table 1

Comparison of Pre-Survey and Post-Survey Responses on Campers' Knowledge and Interest in Natural Resources

Question	Pre-Survey	Post-Survey	Difference	P-Value
I want to pursue higher education	3.83	4.04	0.21	0.4263
I am interested in a career in the field of natural resources.	3.50	3.57	0.07	0.7682
I am familiar with the various career paths available in the field of natural resources.	3.46	4.13	0.67	0.0139
Environmental science	3.12	3.88	0.76	0.0074
Natural resource conservation principles	2.84	3.96	1.12	2.201E-05
Outdoor recreation management	3.04	3.92	0.88	0.0041
Water	3.76	3.92	0.16	0.4493
Wildlife Biology	3.76	3.96	0.20	0.4285
Plants/Vegetation	3.52	3.58	0.06	0.8362
Soil	2.84	3.54	0.70	0.0306

The survey also assessed campers' interest in natural resource activities (e.g., clubs, volunteering) and careers, with responses categorized as Yes, No, or Unsure. Results showed a significant post-camp increase in participation interest: campers interested in natural resource activities such as volunteer work, clubs, camps, and recreation, doubled from 8 to 16, while those uninterested dropped from 13 to just 1, indicating a strong positive impact (Figure 1).

However, career interest followed a different trend. The number of campers interested in natural resource careers decreased from 4 to 2, while those uninterested dropped from 8 to 4. Notably, the number of "Unsure" responses increased from 12 to 17, suggesting that while the camp deepened awareness and understanding, it also exposed the complexities of these careers, prompting some campers to reconsider their options (Figure 2).

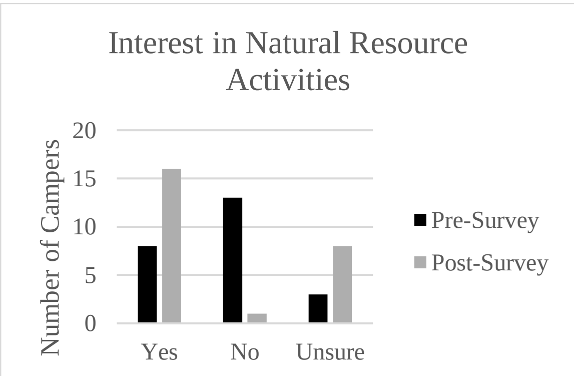

Figure 1: Evaluation results for interest in natural resource activities, such as volunteering, clubs, and recreation.

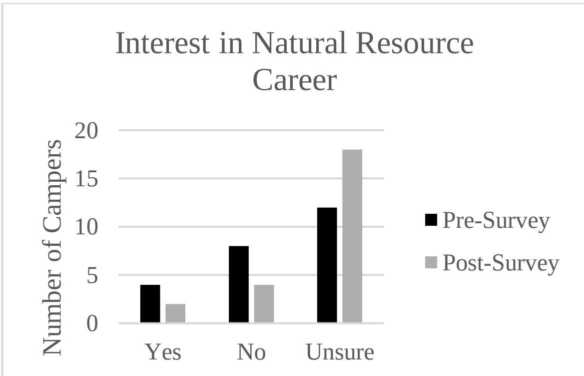

Figure 2: Evaluation results for interest in natural resource careers

Discussion

These results suggest that the camp effectively enhanced participants' understanding in these subject areas. However, changes in interest in higher education, career aspirations in natural resources, and knowledge of water, wildlife biology, and plants were not statistically significant ($p > 0.05$). While some areas showed slight increases, the results indicate that further engagement or long-term exposure may be needed to influence career and educational aspirations. Some ideas that we have had about camp as we move it forward is to involve more public speakers/demonstrations at camp that would showcase the various public land management organizations in the United States and incorporating more engaging hands on activities for the areas that scored lower.

Overall, the findings suggest that the camp successfully improved participants' knowledge in key natural resource topics, reinforcing its educational value. It is exciting to see that participation in this camp helps to change perceptions on natural resource careers in an overall positive way.

Policy engagement to enhance future American rangeland systems: implications for the IYRP 2026

Coppock, DL

Professor Emeritus, Department of Environment and Society, Utah State University, Logan, UT USA 84322

Key words: Loss of rangeland social-ecological systems; rangeland-relevant legislation; Society for Range Management

Abstract

The purpose of this paper is to explore issues that American rangeland professionals regard as most important in supporting sustainable rangeland systems. Impetus for this work is provided by the pending International Year for Rangelands and Pastoralists (IYRP), to be celebrated in 2026. One of the goals of the IYRP 2026 is to raise awareness about the challenges facing global rangelands. The American situation described here provides one example we can learn from. The objectives of this work include: (1) Summarizing recent findings from surveys and workshops conducted during 2022 to 2024 where the participants—largely members of the Society for Range Management (SRM)—ranked priority rangeland problems to be tackled; (2) reviewing historical and current aspects of policy environments that affect contemporary problem-solving on American rangelands; and (3) clarifying how progress in policy-related problem solving could be linked to the IYRP 2026. Findings are summarized as follows: (1) American range professionals see loss of rangeland systems as the key challenge, and interventions are needed to preserve open spaces and support new generations of resource users; (2) improved policy making and stakeholder collaborative processes are the main interventions to address these key challenges; (3) recent policy opportunities abound at local, state, and federal levels that could promote sustainable rangeland systems, but how best to engage policy making and document impacts remains somewhat of an enigma; and (4) in the context of action planning for IYRP 2026, it is proposed that a process of generating political proclamations that underscore the multiple values of rangelands to society are a useful first step that can better connect SRM sections to local and state-level political entities.

Introduction

Policy can be defined as "a course or principle of action adopted or proposed by a government, party, business or individual" (Anon 2024). Policy is complex and embraces many levels of engagement. In the USA, this includes players such as the federal, state, and local governments. Various policy objectives can be complementary or contradictory. Despite that policy is very important for rangeland preservation and stewardship, attention devoted to policy by stakeholders is surprisingly limited, especially in the world's more affluent nations (Holechek 2013). One major reason for this is the strongly eco-centric orientation of range science and management. Tertiary education in natural resources at American Land Grant universities has been founded on conveying technical aspects of vegetation assessments and livestock production; policy is typically left to social science departments rarely engaged by applied ecologists.

In the run-up to the International Year of Rangelands and Pastoralists (IYRP) 2026, a multi-faceted approach has been embraced by rangeland advocates and change agents tackling a wide array of ecological and social issues (IYRP 2024). Awareness-raising among key stakeholders, the public, and political decision makers is a prominent goal. As part of this effort, work was undertaken here to help clarify a policy environment for American rangelands so that an action agenda can be formulated in support of sustainable rangeland systems for the future.

Methods

Materials summarized here were created from 2022 to 2024 based on several approaches. Modest numbers of email surveys and several workshop deliberations, largely involving members of the Society for Range Management (SRM), were mined for policy-relevant information. Text from key aspects of draft federal legislation was reviewed. State-level perspectives have been focused on Utah, a classic example of a western, public-land entity where a small percentage of the landscape is under private ownership; the Bureau of Land Management (BLM), US Forest Service (USFS) are the federal stewards of most of the remainder (Leydsman-McGinty 2009). These efforts in tandem represent only a very preliminary, exploratory, qualitative synthesis that may help rangeland stakeholders chart a way forward for more effective policy engagement.

Results

National SRM Email Surveys and Workshop Deliberations

An email survey was sent to all 21 SRM sections (SRM 2024) during September and October 2022. In theory, this survey reached hundreds of potential respondents. Questions were open-ended and asked people to identify priority challenges facing rangelands as well as priority interventions to address the challenges. There were only 13 completed surveys submitted by Americans, with another 23 from Canadian and Mexican SRM members. Key results from the Americans are shown in Table 1. While the survey response rate was poor, results were broadly validated by over 50 participants at a follow-up workshop in February 2023, held at the annual SRM conference at Boise. Furthermore—although not emphasized here—data collected from Canadian and Mexican respondents were generally similar as well. In sum, it was concluded that the prominent gaps overall focused on the need for more effective policies, expanded outreach, education, and strengthened stakeholder networks.

Table 1. Top five challenges and intervention priorities (ranked) for American rangelands as revealed by 13 SRM stakeholders in 2022

Priority Challenges	Priority Interventions
1 Loss of rangeland systems	1 Policies preserving rangelands and livelihoods
2 Public and policy makers uninformed	2 More public and policy outreach needed
3 Climate change and ecological problems	3 Strengthen management at local levels
4 Better manage expanding recreation	4 Need to update federal regulations
5 Engage more resource users	5 Need to improve stakeholder networks

Utah Section SRM Group Discussions

Another effort to seek feedback on priority actions needed to sustain rangelands more locally was provided by an annual meeting of the SRM Utah section during November 2023. Forty-five attendees were assigned into nine groups of five people each for 30-minute discussions. Results were ranked with up to three categories, scored from most to less important (i.e., 3, 2, 1), and summarized. The top two needs for action in Utah were: (1) Developing more effective stakeholder networks on projects of mutual concern (16 ranked points overall), and (2) improvement of state and federal collaborations (15 ranked points). Four other needs followed more distantly, including: (1) Improved management of outdoor recreation (8 points); (2) expansion of public education concerning rangelands (6 points); (3) improvement of internal agency management processes (i.e., staffing and priority setting) for the BLM or USFS (6 points); and technical aspects of rangeland management and resource monitoring (5 points).

Historical Policy Environment

The foundational policies that still influence contemporary resource access and use in the rangelands of the western USA were first enacted over 150 years ago (Holechek et al. 2011). A vast, unsettled landscape governed by territories comprised most of the national endowment West of the Mississippi River. Federal Acts from congress relevant to rangelands began with the Homestead Act (1862) that allocated 160-acre parcels to people to encourage farming and the acquisition of private land. The Transcontinental Railroad Act (1862) promoted rural development, emigration, and market development. Government was slow to realize, however, that only small segments of land in the West were suitable for cultivation, hence grazing issues per se received little attention until later. Attempts to amend policies to enlarge homestead sizes or incorporate stock-raising on farms led to resource degradation because fodder resources were mismatched with livestock production needs.

The Forest Reserves Act (1891) and the Taylor Grazing Act (1934) enabled newly minted federal entities to control access to remaining public lands by curbing indiscriminate logging and overgrazing. Today, for example, ranchers in the western USA often graze livestock on a combination of private and public lands. Access to the latter is governed by permits for the use of allotments that are regulated to promote more sustainable utilization of forage. Agencies that oversee this resource use include the US Forest Service (USFS) at higher elevations and the Bureau of Land Management (BLM) at lower elevations. The USFS and BLM remain very influential in Utah.

Current Policy Environment

Using the State of Utah as an example, it is fair to say that there is considerable political tension today between state interests and federal interests concerning access to, and use of, rangeland resources. This occurs over a backdrop where the State of Utah controls roughly 20 percent of the state's land area and the US government controls most of the remainder. To illustrate conflict, for example, the State of Utah has recently sued the federal government for control over BLM lands (Schoenbaum and Brown 2024). This effort is a rekindling of past litigation; legal experts contend that the current lawsuit has little chance for success. There are other avenues for federal policy intervention for Utah rangelands. A prominent example is the omnibus Farm Bill, renewed every five years since the 1930s (Myers 2022). Traditionally the Farm Bill has not given much attention to rangeland, but this is changing. SRM submitted remarks in 2023 for the current update of the Farm Bill that is still ongoing (Reini, pers. comment). Requests from SRM include more Farm Bill support for: (1) Range conservation programs—including federal match for establishing land trusts; (2) innovative management technologies; (3) specialized education for range users including facilitation of intergenerational transfer of ranch operations; and (4) strengthening federal land-management agencies. Other range-relevant federal legislation has recently received attention, including the bipartisan North American Grasslands Conservation Act, introduced in the US House of Representatives in October 2024 (NAGCA 2024). The goal of the NAGCA is to foster landowner driven, voluntary, incentive-based programs to help conserve and restore over 125 million acres of critically imperiled grasslands and associated ecosystems, also with attention to livelihoods that includes farmers, ranchers, recreationists, and Native Americans. The focus of the NAGCA is on private lands. Administrative details of the NAGCA remain under debate. Extended congressional delays for both the Farm Bill and NAGCA are expected under the current atmosphere of political uncertainty (Reini, pers. comment).

Again, using Utah as an example, there are state- and local-level policies and actions targeted towards rangelands. The UGIP (Utah Grazing Improvement Program) funded by the Utah Department of Agriculture and Food, has provided support for ranch-level resource management innovation for almost 20 years (UGIP 2024). The UGIP is also under consideration for expansion into neighboring states given the success in Utah. Recent Utah legislation illustrates a novel embrace of ecosystem-level perspectives concerning sustainable management of the Great Salt Lake (GSLR 2024). Efforts to divert more water to the lake will ultimately have implications for water conservation on rangeland landscapes for both public and private lands. The need to recruit the next generations of ranchers seems to be addressed, at least in part, via educational outreach programs sponsored by the Utah Farm Bureau Federation, an NGO (UFBF 2024). Finally, local (county level) actions in the form of voter-approved bonds have recently taken hold in a few areas where peri-urban or ex-urban development threatens open space. Bond funds are used to purchase conservation easements (CC 2024).

Discussion and Conclusions

Feedback from national and local (Utah) sources suggests that dominant challenges for rangelands are social rather than technical in nature. The national input amplified policy and outreach to promote sustainable rangeland systems. The Utah input, in contrast, noted more need for improved stakeholder networks and inter-agency collaborations on-the-ground. This distinction between national and Utah perspectives makes sense. Honing this down further one might surmise in a synthesis that interventions are needed to preserve working rangeland landscapes, because failure to do so means that social-ecological systems will collapse. Policy-scale actions can help conserve land and fortify a new generation of resource users. Local-scale actions like stakeholder engagement and improved inter-agency collaborations play support roles in this process.

If we “connect the dots” between the synthesis above and elements of the current policy environment, several aspects of each seem to match up; it appears there is momentum towards increasing policy awareness about rangelands in the USA. Recent efforts at the federal level to raise the profile of rangelands in the Farm Bill as well as submission of a Grasslands Act are both timely. Of note is the potential provision of more money in the Farm Bill for the purchase of conservation easements via match from the McAllister Fund; lack of such resources makes open-space acquisition in Utah a struggle (Snider, pers. comment). The possibility of funding support for grassland conservation more broadly in the context of the Grasslands Act has even greater national implications. That state legislators in Utah now debate regionally scaled management of the Great Salt Lake is also encouraging.

How do these findings relate to the IYRP? A major goal of the IYRP is to raise awareness about rangelands worldwide among policy makers and the public (IYRP 2024). One impression from this work is that while rank-and-file SRM members appreciate the need for helpful policies to better navigate the future, there are few examples of SRM members actively engaging policy makers. Documenting policy impact thus becomes difficult at best. Policy engagement, rather, is left to NGOs and special interest groups. At the February 2025 annual meeting of SRM at Spokane, WA, a symposium will craft an IYRP action plan for North America. One of the key components of the action plan will focus on creation and delivery of short proclamations for political leaders in local and state governments. Editable templates will celebrate rangeland values for the public. Each SRM section will connect with policy makers to enable this process to occur, helping to build policy-relevant capacity for SRM. Other efforts are being made to bridge gaps between policy makers and SRM at state and federal levels (Reini, pers. comment). This all captures the spirit of the IYRP.

Adapting decent work (SDG 8) for sustainable pastoral systems: meanings and challenges of decent work for Mongolian herder women

Bayarbat, T[1]; Fernández-Giménez, M[2]; Ulambayar, T[3]; Jamsranjav, C[4]

Key words: gender; International Labour Organization (ILO); pastoralist identity; sustainable pastoral systems; herder women's empowerment

Abstract

The UN Sustainable Development Goal 8 includes "decent work for all" as a sustainable, inclusive economic growth component. The International Labour Organization (ILO) defines decent work as productive in conditions of freedom, equity, security and human dignity. Yet, almost no research or development initiatives have considered how decent work applies to pastoral systems. Therefore, we explore the meanings of "decent work" for women herders in Mongolia and compare these meanings with the ILO's criteria. We facilitated two workshops with women specifically focused on decent work (n=34) in 2023. For Mongolian herder women, "decent work" means "meaningful work" related to their cultural heritage, pastoralist identity, personal satisfaction, and the interdependent health of land, livestock, and people. "Opportunities for learning and professional development" also emerged as a key meaning not captured in existing ILO standards. Herder women face numerous barriers to decent work conditions, including long working hours, caregiving responsibilities, social isolation, domestic violence, lack of social and health services support, and limited alternative employment opportunities. Yet, ILO's decent work indicators and Mongolia's legal frameworks fail to address these issues adequately. This exploratory research highlights the mismatch between ILO's generic decent work criteria and indicators and the lived reality of pastoralism. Given the paucity of decent work research in pastoral systems, this study has broad relevance to pastoral systems globally as governments, donors and NGOs consider how to support socially just and sustainable pastoralism.

Introduction

The concept of "decent work" is defined as "productive work for women and men in conditions of freedom, equity, security, and human dignity" (Oya 2015, p.8). According to the ILO (2018), promoting jobs and enterprise, guaranteeing rights at work, extending social protection and promoting social dialogue are the four main pillars of decent work. With the help of these pillars, all workers should be able to access social security, fair pay, safe working conditions, and the opportunity to influence decisions that impact their professional lives (Aufderheide et al. 2013). Yet, putting these ideas into practice can be difficult, especially in the rural and agricultural sectors. Employment in rural areas is often seasonal and informal, so the ILO's indicators and standards frequently fail to adequately address these conditions. These difficulties are made worse in the case of mobile pastoralism, especially among women. Women pastoralists are responsible for reproductive labour (child rearing and household management) and productive labour (herding and processing livestock products), as well as community roles. These overlapped responsibilities are frequently unacknowledged and unpaid, which makes it more difficult to implement decent work standards (Köhler-Rollefson 2012). At the same time, the growing global emphasis on sustainability in rangeland management is making the issue of decent work for pastoralists increasingly relevant. Furthermore, both the International Year of Rangelands and Pastoralists (IYRP2026) and the newly adopted International Year of the Woman Farmer (IYWF2026) highlight the challenges and importance of women's roles in pastoralism.

In this article, we address a gap in the literature on decent work in pastoral settings, focusing on Mongolian herder women. This study uses qualitative research methods to illuminate what decent work means to Mongolian women herders and the challenges to achieving it. We also aim to contribute to a deeper understanding of the lived experiences of herder women in Mongolia and to suggest actionable implications that respond to their specific needs in achieving decent work.

Methods

We organised participatory workshops with 34 herder women aged 20–70 in two provinces, Arkhangai and Bayankhongor, each with distinct ecological environments. Arkhangai lies in the Khangai Mountain region, with rich pastures and dairy production. In contrast, much of Bayankhongor lies in the Gobi desert-steppe zone, where cashmere from goats is a primary source of household income. In the workshops, we used the World Café method (Löhr et al. 2020) to foster deeper discussions on specific questions related to decent work. Discussions were audio-recorded, transcribed, translated into English and analysed using grounded theory (Charmaz 2006). Data analysis began with open coding, generating 165 initial codes, redefined to 291 after a second review of coding. We then conducted axial coding, connecting codes to create key concepts that define "decent work." In the final stage, we organised axial codes to identify a theoretical framework with nine main meanings of decent work as explained by herder women.

Results

The nine key meanings of "decent work" for Mongolian women herders identified through participatory workshops reflect cultural identity, a sense of responsibility for herd and pasture health, and economic and social aspirations.

1. **Meaningful Work:** Meaningful work for women herders is work that inspires pride in one's occupation and provides physical and mental enjoyment of one's herding lifestyle. During workshops, a woman herder expressed "*Decent work is work that fulfils the mind, body and economy of the household"* (Bayankhongor, May 2023). Pastoralism is a way of life, identity, culture and tradition, and these meanings are critical to a sense of purpose and dignity.
2. **Healthy Land:** The health of livestock, herders' livelihoods, and the long-term persistence of their nomadic lifestyle depend on healthy and productive pastures. This dedication to environmental sustainability includes avoiding excessive grazing by moving seasonally, safeguarding nature, and guaranteeing the land's ability to sustain its herds in a healthy pasture. Furthermore, healthy land is deeply connected with the Mongolian cultural concept of *nutag* (homeland) as an interconnected web of land, livestock, people and other more-than-human beings (Baival 2012, Ichinkhorloo 2017). Moreover, in contemporary Mongolian, the word *nutag* also fluidly embodies a much wider range of things and ideas, such as the environment, nature, resources, history, origin, authenticity, identity, sovereignty and spirituality (Bumochir 2019). Women herders acknowledge their cultural role in the countryside and identify themselves as custodians of the land.
3. **Healthy Livestock:** The health of their herds directly impacts herders' economic stability, as healthy livestock produce high-quality products that lead to a stable income. For centuries, herder women have been taking care of their livestock, preparing for natural disasters, tending baby animals and maintaining the overall wellbeing of their livestock. Additionally, most of their household income comes from livestock products, including dairy products and cashmere, which are made by women herders. During the workshop, participants stated *"…Our livestock should be fat and strong [healthy] so that the prices will go up"*; on the other hand, another participant said "*These cattle are your cash; sheep are your pennies*."
4. **Sufficient and Stable Income:** A sufficient and stable income is a key element of decent work globally, including for herder women in Mongolia. Herder livelihoods depend on environmental conditions and are

vulnerable to drought and winter weather disasters, and livestock income is highly seasonal. Herder women emphasised their interest in adding value to raw livestock products to market them at higher prices. To facilitate this, appropriate training and, in some cases, machinery (e.g., butter churns, knitting machines) are essential. Women also spoke of the need to diversify rural economies to include alternative, non-herding jobs, especially for young people.

5. **Human Health and Safety:** Women herders mentioned having a healthy body is essential to their daily lives. Ensuring a healthy body and human safety requires the ability and resources to care for personal and family health, such as regular medical check-ups and access to adequate community health services, including local hospitals, and safe working conditions.
6. **Social Safety Net and Welfare:** The existing legal framework in Mongolia characterises herders as self-employed individuals, accommodating them in the voluntary social insurance scheme (ILO 2024). To get unemployment benefits, pensions and other social protection services, herders must pay their taxes accordingly. However, in 2020, the social insurance coverage rate for Mongolian herders was 16.4%, and health insurance coverage was 25.1%, although mandatory (ILO 2022). According to women herders in both workshops, an incomplete understanding of social and health insurance schemes leads to a lack of enrolment and payment, resulting in a lack of coverage and social protection services.
7. **Opportunity for Professional and Personal Development:** Women herders seek professional and personal development opportunities that allow them to improve their skills in value-added product processing, adapt to new technologies, and face daily challenges. Many mentioned that "*khorshoo*" (cooperatives) play a key role in supporting herders to work together and overcome challenges. Women also expressed interest in leadership and literacy training.
8. **Social and Cultural Participation:** Many herder women experience social isolation due to their remote locations and home-based care work. Participating in community social and cultural activities helps women feel engaged with society and a part of their community. Participating in these events also gives them the chance to network with other herders to accomplish common goals, like preparing hay and feed together, and exchanging livestock and human health-related traditional and practical knowledge.
9. **Herders' Rights:** Last but not least, herder women highlight legal protections for herding communities, including the rights to education, healthcare, pension support and protection of pastures. They advocate for government investment in local economies, ensuring fair rights and opportunities for all herders. Furthermore, culturally nomadic people move seasonally to keep their pasture and animals healthy; thus, they highlight the right to move freely in the countryside. One woman mentioned: "*We have freedom. We can move wherever we want"* (Bayankhongor, 2023). Therefore, it is important to acknowledge their cultural and human rights at the same time to maintain sustainable pastoralism.

Discussion

Mongolian herder women hold a holistic view of decent work that integrates the health and wellbeing of humans, livestock and the environment as interdependent elements. Furthermore, women herders' experiences highlight the need for gender-sensitive approaches within decent work standards. Pastoral women's triple-burden workload—care for home, including children and family members; care for animals and product processing; and care for the community—significantly impacts women's health and may contribute to rural gender imbalances that threaten pastoralism's future (Köhler-Rollefson 2012, FAO 2023, Fernández-Giménez et al. 2024). Our findings align with research that emphasises the challenges many pastoralist women face, including limited access to productive resources, adaptation to climate change and the undervaluation of their work, and therefore the need for gender-sensitive policies that address the inequities (Anbacha & Kjosavik 2019, Po & Hickey 2018, Wangui 2014, Flintan 2008). Literature on rural social protection emphasises the importance of adapting social safety nets to the unique risks faced by rural women, whose contributions to pastoralist households often go unrecognised (Po & Hickey 2018).

To conclude, Mongolian herder women's understanding of decent work extends beyond ILO's four pillars—productive work, rights, social protection and dialogue—by highlighting *meaningful work,* the *interdependence of healthy land, livestock and people* in pastoral work settings, and women's desire for life-long *professional development opportunities.* These additions highlight the importance of intertwined occupational and cultural identities. In supporting herders' holistic vision of decent work, we recommend that ILO standards reflect the interconnected health of people, livestock and land and address social issues specific to herding community cases, as there is a broader challenge in operationalising decent work standards and indicators in rural and smallholder agricultural systems throughout the world (Oya 2015).

Acknowledgments

Funding for this research was provided by a Fulbright Global Scholar Award. The Sustainable Fibre Alliance (SFA) and the Nutag Action Research and Training Center supported the participatory workshops. We greatly appreciate and acknowledge all the participants in this research who shared their experiences, and the support of local officials and professionals in the study provinces.

Abstract
Rangelands are the cornerstone of African pastoral production systems and rangeland health (RLH) is vital for the health of livestock and the people who depend on them. RLH is integrally linked to actions of livestock, humans, climate and management applied. Cognisant of this, the HEAL (One Health for Humans, Environment, Animals and Livelihoods) project has been demonstrating how RLH can be integrated into One Health interventions at a local level in pastoral areas of Ethiopia, Kenya and Somalia. HEAL, a 12-year project started in 2019 with funding from Swiss Development Cooperation, reshapes service delivery into One Health Units (OHUs), which provides a sustainable, demand-driven and cost-effective integrated human, animal and RLH services. Key actors in implementation of OHUs are community-based health workers. In Ethiopia, these include the well-established systems of community-animal health workers (CAHWs) for livestock and health extension workers (HEWs) for humans, but there is no equivalent system for rangeland. In response to this, HEAL is developing a community-based rangeland health workers (CRHWs) system. A central pillar of this is piloting CRHWs, following a review of current practice, lessons learned from CAHWs and HEWs, and consultations with experts and communities. Initially, CRHWs are providing information and raising awareness on invasive species and establishing community RLH monitoring system for these. To instil opportunities for CRHWs to be self-supporting, nurseries for growing and selling grass and tree seedlings were established in agreement with community leaders. This paper shares experiences of piloting CRHWs and how this contributes to broader development and investment in RLH. Collaborative design from the beginning was important for increasing likelihood of uptake by government and communities besides considering sustainability and financing. Research played important role in assessing opportunity and application of CRHWs, developing support training materials and for sharing lessons learned.

Introduction
Rangelands are cornerstone of African pastoral production systems (ILRI et al. 2021). Thus, rangeland health (RLH) is vital for livestock and human health and is integrally linked to actions of livestock, humans, climate and management applied (e.., sustainable grazing; build soil organic matter). Nevertheless, East African rangelands face many problems like climatic fluctuations, drought and others. Ethiopia also has critical shortage of qualified rangeland experts with a high staff turnover (EIAR, 2017). One Health (OH) has also received increasing attention in recent years as an integrated approach bringing together human, animal and

ecosystem-environmental health (Cunningham et al. 2017). The HEAL (One Health for Humans, Environment, Animals and Livelihoods) has been demonstrating how environment/rangeland health can and should be integrated into One Health (OH) interventions at local level in pastoral areas of Ethiopia, Kenya and Somalia. The HEAL was established in 2019, with funding from Swiss Development Cooperation and is a 12-year project that seeks to establish sustainable, demand-driven and needs-based One Health Units (OHUs), as cost-effective, innovative, integrated service delivery models. Key actors in the implementation of the OHUs are community-based health workers, which provides cost-effective and integrated human, animal and rangeland health services to local communities. In Ethiopia, there is a well-established system of CAHWs for the livestock health and a strong and well-functioning system of HEWs for human health at community level. However, there is no equivalent structure for rangeland health. A study was undertaken to assess possibility of establishing a system of CRHWs and its operational modality in Ethiopia.

Methods

The study was carried out in HEAL project areas of Somali and Oromia Regional States of Ethiopia (Liben, Dawa and Borana zones). The study comprised rapid assessment; validation of assessment findings through participatory workshops; training and follow up of CRHWs for implementation. The rapid assessment included literature review with focus on HEP/HEWs, CAHWs and CRHWs which was followed by key informants interviews (KIIs) using checklists with qualified, and knowledgeable individuals in livestock, humans and RLH. The KIIs were undertaken with community elders, heads/experts of Tuft University and Vétérinaires Sans Frontières (VSF), researchers/ national rangeland coordinator, livestock /pastoral extension heads at different levels, HEAL field coordinators and Amref Health Africa staff. A total of 28 KII interviews were conducted. Two workshops were undertaken to validate assessment findings, agree on next step including selection of CRHWs, income sources of CRHWs etc. Preparation of training materials and selection of CRHWs in each kebele (lowest administrative unit) was undertaken. CRHWs were trained on overview and experiences of OHU; management of invasive species and rangelands; community awareness and monitoring; nursery management; practical visits. Follow up of piloting CRHWs system was undertaken by HEAL Project staff and partners.

Results

Assessment report on possibility of establishing CRHWs system was organized covering different topics.

Health Extension Program (HEP)/HEWs: The Ethiopian government established a 20-years Health Sector Development Programme in 1997. After implementing the first five-years plan, health sector performance improved but the ability to deliver essential services in rural settings was less successful (EFMOH 2008). The government introduced HEP, a primary care delivery strategy, to address the challenges and achieve WHO MDGs. HEP was launched at scale in 2003 with 17 health extension packages for rural regions, which were later adapted for towns and pastoral areas. The program focused on promotional and preventive measures based on training and awareness creation. Sustainability required institutionalized and integrated health program with developed human capacity, infrastructure, decentralized management and political commitment. HEWs are selected in a participatory way from community members using selection criteria and are given training for 1 year. Model families and non-paid community health voluntaries support HEWS. The system is recognized globally (Bowser *et al*., 2023).

CAHWs: Establishing and maintaining nationwide animal disease surveillance systems is a major challenge in many developing countries due to various reasons. Use of CAHWs selected in participatory way from community using selection criteria was found as the best option for preventive and primary curative purposes. It has demonstrated remarkable achievements. Its sustainability depends on: income generated from their livestock health services, connections with local drug suppliers, level of training and supervision by veterinary statutory bodies, institutional arrangements for legalization and promotion of the services delivered and entrepreneurial skills (OIE 2013).

Key lessons learnt from HEWs and CAHWs: the long journey with many ups and downs; the need to start with the HEAL project; sustainability; good preparations, engaging community and relevant actors from beginning for buy-in of the concept; use of multidisciplinary approaches; community access to services in times of need; awareness creation etc.

Organization of CRHWs system: The response of the KII indicated that CRHWs system needs to be established in Ethiopian rangelands as we have limited experienced professions in rangeland management resulting in the lack of adequate service delivery particularly at the community level. The rangelands are degrading rapidly, requiring faster action. As CAHWs (livestock) and HEWs (humans) are already collaborating in the OHUs, supporting them by including CRHWs is essential. It is suggested for CRHWs to undertake simple tasks within the preventive and promotional general umbrella: **rangeland health education and communication** (e.g., awareness raising, community mobilization, sharing information on invasive species/rangeland status); **Rangeland evaluation and monitoring c) rangeland management and rehabilitation** (e.g., involve in degraded area identification, suggest interventions with community and inform responsible body timely). The aim of the CRHW system is not to replace NRM services but to complement them. Their role in OHU will include: support HEAL project officers in planning, site selection, implementing, training, awareness creation etc. The respondents and review work indicated that CRHWs selection criteria can vary among different Regions of Ethiopia. However, the important are: a) be a kebele resident and know the area well, b) 25 years of age or older and own livestock, c) have basic reading and writing skills, d) have time, willing and committed to work and serve community, e) pro-development, f) trustworthy and respected by different actors, g) have good relationships with people at different levels, h) willing to learn and take action, i) have some training related to rangelands and NRM. They should be selected in a participatory way from the community based on selection criteria.

Institutionalizing CRHWs: The significance of institutionalization of CRHWs system was indicated in the study results. The participants suggested three options for making the CRHW system sustainable. First, there is no need to establish a separate structure. Instead, they can be under the kebele natural resource management administration office, or the livestock production and marketing office (embedded in the existing system). The second option is formal institutionalization by having a focal person from the agricultural or pastoral development office at the region, zone and district levels for follow-up, supervision and other issues. These government officers should help with training and regular follow-up. The third option is for CRHWs to operate within a local rangeland management institution, which must be adapted to each context, considering specific sociocultural, political, economic and environmental factors. Therefore, one-size-fits- all model does not work. Potential sources of income for CRHWs include: i) advising, guiding and getting involved in bush control ii) collecting forest products iii) seedling production or collecting seeds of native plants for rangeland improvement, iv) participating in rangeland monitoring and reporting, v) training other community members, vii) getting involved in apiculture, viii) playing role in identifying rangeland plants of medicinal and other economic value. Among these, the HEAL project focused on supporting nursery establishment in consultation with the administration and CRHWs. Budget is needed for different purposes (e.g,, training materials preparation, training, equipment), Sustaining factors of the CRHWs include i) individual and community commitment, ii) sources of income, iii) legal status, iv) supervision, v) equipment, vi) political commitment, vii) public-private partnership.

Opportunities (e.g., rehabilitating degraded rangelands to create favourable situation for livestock production including better control of invasive and noxious plants, livestock feed resources, increasing rangeland production and productivity) and challenges (e.g., ownership, resource limitations. ensuring regular monitoring, accountability and coordination, increased rangeland privatization) of the CRHWs system and its implementation were also explored and documented through the KII and literature review. Working at the community level, the HEAL project can operationalize/pilot the system by discussing with local bodies at kebele rangeland unit and district levels. Piloting may not require specific legislation and policy. However, there will be a need to discuss policy issues with concerned officials once the CRHW system will be ready to scale. Also piloting and evidence generation, there will be a need to develop national minimum standards and guidelines for designing the system which include understanding the context; community dialogue and selection, training CRHWs, monitoring and refresher training and development of national training curriculum.

Validating findings, selecting CRHWs and training: 27 people attended the participatory workshops in Moyale and Filtu which validated the findings of the assessment report, included additional selection criteria and income source, and agreed on the way forward. Twelve CRHWs (6 from Borana and 6 from Dawa and Liben zones) were selected and trained for six days. The implementation of CRHWs system is handled by HEAL project staff and partners at different levels.

Discussion

The study showed that there are no community-based rangeland health workers in Ethiopia. The positive response of all key informants on the CRHWs system, lessons drawn, and information gathered from the HEP/HEWs and CAHW implementation and the review results have paved the way to pilot CRHWs system. The HEAL project has provided the foundation for beginning the pilot phase as it is assessing the value of an integrated service delivery model among pastoralist communities. To date, the rangelands component of the HEAL project has focused on participatory rangeland management and, while this has laid a solid foundation for improved rangeland management in the community, it did not allow to fully integrate rangeland health into the community-based service delivery model proposed through the OHU. Accordingly, piloting a CRHW system could take the rangelands component a step closer to embedding rangelands health at the local level and pave the way for developing private sector rangeland service provision in Ethiopia. It is also worth looking into the possibility of linking with existing initiatives like the pastoral safety net program. The CRHWs could help rationalize the program and other resources at the community level by targeting these resources where restoration is feasible and offers tangible benefits to pastoralists.

The progress made so far have shown that it is possible to develop a system of CRHWs. The project is maintaining a comprehensive documentation during the pilot period which will lay the foundation for scaling up. The short-term plan should start with what is in hand and develop mid- and long-term plans so that the CRHWs stand on their own. Collaborative efforts among different actors is highly needed. Institutionalizing the system, supporting the CRHWs system to stand on its own (sustainability), equipping the CRHWs so that they generate their own income source are founding blocks for the system's success. It has also to be linked to the broader development of the pastoral and agro-pastoral communities whose livelihood depends on livestock production and utilization of different ecosystem services from the rangelands.

Understanding conservation of Orans in India through the lens of institutional bricolage

Majumdar, S[1]; Nandigama, S[2].

[2]Associate Professor, Department of Humanities and Social Sciences, BITS Pilani, Pilani Campus, Rajasthan, India.

Key words: Orans; Sacred Groves; Rajasthan; Rangelands; Conservation

Abstract
'Orans' are centuries-old traditional grazing lands of Rajasthan, India, that are preserved and conserved because of spiritual beliefs and cultural values of the local communities. Due to religious sanctity, the villagers do not cut trees or poach animals in the Orans. However, they use them to graze their animals for which there are strict guidelines regarding the period of grazing and the type of animals that are allowed to graze. In the arid state of Rajasthan, Orans play a vital role in supporting the livelihoods of the local livestock-based communities. They provide not only grazing grounds but are also a source of water, fodder, firewood, wild fruits, medicinal herbs and other utilities. The management and conservation of Orans heavily depend on the active participation of local communities. Therefore, it is crucial to consider the local socio-cultural practices that these communities have been practising from generations to conserve Orans. While formal institutional mechanisms deployed by the government and forest departments are important, understanding the informal dynamics of local actors are equally vital. Hence, this paper finds that the effectiveness of institutions depends not only on their formal design but also on their alignment with existing local practices. This process is called Institutional Bricolage that involves creative recombination and adaption of institutional elements to fit local contexts. The paper analyses the concept of Institutional Bricolage in the context of Oran conservation and management practices that will seek to understand the interplay between informal and formal institutions in natural resource management, highlighting the need to blend formal institutional frameworks with informal local practices for effective conservation outcomes. This paper emphasizes the importance of recognizing local agency and indigenous knowledge systems in conservation practices of rangelands, advocating for context-sensitive approaches to conservation policy in India and beyond.

Introduction

The state of Rajasthan is situated in the northwestern part of India and is known for its arid climate and desert landscapes, where water scarcity, hostile weather conditions and increasing desertification pose serious challenges to its inhabitants. The scarcity of vital resources such as water and fertile land demands careful management practices, many of which are embedded in the socio-cultural customs of the local communities. The *Orans* or *Devbanis* are one such example of community-based sustainable resource management. Central to the Rajasthan's pastoralist lifestyle, *Orans* are the sacred groves or rangelands traditionally protected and managed by the local communities (Singh 2016). In Rajasthan, agriculture is particularly challenging due to extreme weather conditions, poor soil fertility and low rainfall, forcing many rural communities to rely on livestock as a viable source of livelihood. Animal husbandry not only provides a steady source of income[1] but is also the much-needed insurance against frequently occurring scarcity conditions in Rajasthan. Since ancient times, the communities of Rajasthan used to keep aside a certain patch of land as grazing grounds that also contain water bodies like ponds or waterfalls in order to support their livestock. These lands are called '*Gauchars*' (*Gau*- Cattle, *char*- to graze). To discourage cutting of trees and exploitation of the resources, some of the *gauchars* or grazing lands were dedicated to the local deities or supranatural powers who are believed to be responsible for the protection and well-being of these sacred places and organisms residing within them (Chaudhry, Bohra and Choudhary 2011). *Orans*, thus, serve as vital natural reserves, offering crucial grazing lands and water sources for the livestock. However, in recent years, the growing demand for livestock and the increasing human population, coupled with surging consumerism and urbanization, have disrupted traditional institutions. This breakdown has resulted in the loss of collective wisdom, ultimately causing significant land degradation and desertification in the region.

Methods

Sacred groves, being cultural and ecological entities, demand a methodology that captures their complex socio-cultural, spiritual, environmental and economic dimensions. Accordingly, this study employed a qualitative, interpretive and ethnographic approach to examine the conservation of sacred groves in Rajasthan, drawing on both primary and secondary data sources. This strategy allows for an in-depth understanding of the narratives, practices and values associated with the rangeland management. The fieldwork for this study was conducted across 6 sacred groves in the *Shekhawati* region and *Dhundar* region of Rajasthan in the districts of Jaipur, Alwar and Jhunjhunu. 25 semi-structured interviews and 3 focus group discussions were conducted for this study. These interviews included elderly villagers, temple priests and women, who are the custodians of oral traditions. Other ethnographic methods such as participant observation and transect walks were also employed to capture the lived realities of the local communities. In addition to engaging with community members, this study also incorporates insights from forest guards, local leaders and elected representatives who belong to or are directly involved with the communities stewarding these rangelands. Their dual affiliations—to the community and to formal governance systems—help illuminate the bricolage between the indigenous practices and state-led conservation efforts. Along with the primary data, the study also used secondary sources such as published scholarly articles, books and governmental reports on the *Orans* of Rajasthan.

Results

The lifeline of the rural communities in Rajasthan, the *Orans,* are facing severe exploitation and destruction. The ever-increasing growing population of livestock is putting immense pressure on the grazing lands. According to the 20th Livestock Census[2], the total livestock population in Rajasthan has grown to 56.8 million in 2019, a significant jump from 32.43 million in 1956. This substantial rise in the livestock population highlights the increased demand for resources and the added pressure acting as a challenge to sustainable management of the region. There has been also a rise in the spread of non-palatable species of the grasses and weeds in the *Orans* such as *Prosopis juliflora* and invasive tree species of *Accacia* due to their faster growth rates and grazing tolerance. Due to these invasive species, an accelerated destruction of the native vegetation in the Orans can be observed. This has a direct impact on the capacity of the *orans* and *devbanis* to support the livestock of the locals on a daily basis.

The traditional beliefs and religious sanctions that once acted as powerful social deterrents have been sidelined due to rapid urbanization leading to over-exploitation of these *Orans.* The younger generations as well as rural communities, influenced by consumer-driven values, no longer hold the same reverence for the *Oran* deities. In addition, State-led forest conservation interventions often pitch formal and informal governance practices against each other. The *Orans* do not fit neatly into a single category of land use pattern in government records

[1] The livestock are good source of milk, meat, manure and transportation.

[2] The Department of Animal Husbandry and Dairying (DAHD) conducts the Livestock Census every five years in collaboration with State Animal Husbandry Departments. The latest 20th Livestock Census was conducted in 2019.

leading to their multifaceted classification as pasturelands or fallow lands or culturable wastelands or as forests lands. This inconsistency in classification results in competing institutional mechanisms creating challenges for local communities to uphold their traditional and spiritual practices. This ambiguity leaves *Orans* vulnerable to illegal mining, encroachment and overexploitation, further threatening their ecological and cultural significance.

Discussion and Conclusion

The *Orans* have been able to survive since time immemorial due to the socio-cultural norms and traditions (Singh 2016) ensuring their safekeeping for the future generations. These sacred customs meant that *Orans* were not subjected to the same kinds of commercial exploitation as the other lands in the locality. Trees could not be cut down indiscriminately, lands could not be exploited, animals could not be hunted on these sacred grounds and the collection of resources such as wild fruits, fuelwood and medicinal herbs were strictly regulated by the local communities. This unwritten code of conduct was passed down through generations by community elders and priests. Historically, the traditional practices such as rotational grazing, periodic restrictions on certain grazing practices, controlled tree lopping and vigilant monitoring by watchmen (Jodha 1990) played a crucial role in safeguarding these pasturelands. However, these community-sanctioned measures have lost their relevance in the face of increasing environmental threats and socio-cultural changes.

A unique aspect of *Orans* lies in the integral role of priests in their conservation and management. Acting as guardians of these sacred forests, priests maintain the socio-ecological divinity that fosters biodiversity conservation. These informal practices and community gatherings associated with *Orans* serve as powerful symbols for fostering social cohesion. These practices are deeply ingrained in local culture and spirituality thus providing a framework for trust, reciprocity and collaboration, which are essential for managing the *Orans* of Rajasthan. These traditions not only reinforce a collective cultural identity but also create mechanisms for conflict prevention and resolution through storytelling and mythological narratives that emphasize respect for nature. Elinor Ostrom (1990) also underscores such values of community-based practices in her design principles.

The analysis of sacred grove governance depends not only on the formal forest governance rules and regulations but also on the informal rituals and taboos. The institutional bricolage (Cleaver 2017) offers a great analytical lens to comprehend the informal institutions and their interplay with formal ones. For instance, communities decide which trees to cut based not just on formal laws but also on traditional norms and their livelihood needs. This flexible approach shows that regulations are not always followed strictly but are interpreted in ways that make sense in real life. This shows that how communities actively negotiate, reshape and reinterpret rules, creating a mix of old and new practices.

Institutional bricolage helps us understand that there is no one-size-fits-all solution. People adapt, change and create systems that fit their needs, cultures, and challenges. Therefore, effective conservation of rangelands in India and globally requires to look beyond written laws and pay attention to cultural values, traditions and daily realities. By respecting local knowledge, blending formal laws with traditional practices and supporting alternative livelihoods, we can create flexible and culturally appropriate conservation strategies. Involving communities, especially women, in decision-making and adopting adaptive management practices ensures that regulations are practical and sustainable. By embracing this nuanced approach, we can achieve conservation goals that are not only ecologically effective but also socially equitable and resilient.

Exploring how gender intersects resilience in the face of chronic uncertainty in the drylands

Ash, R[1]; Wario, H[2]; Wachira, J[2]; Hassan, R[2]; Guracha, D[2]

[1] The University of Tasmania, Tasmania, Australia; [2] Center for Research and Development in Drylands, Moyale, Kenya

Key words: pastoralism; drylands; resilience; climate crises; gender

Abstract

Resilience strategies in African pastoral systems face increasing scrutiny, particularly in the context of climate shocks. This article explores gender dynamics in the generation of resilience in a dryland socio-ecological system and amongst pastoralist communities in Moyale, Northern Kenya. The findings challenge existing assumptions of women's adaptive capacity and traditional gender roles, highlighting women's nuanced understanding of household needs and their ability to innovate during crises through strategies such as community savings groups, fodder production, and diversification. Men's resilience, traditionally linked to livestock mobility and herd management, is undermined by recurring droughts, with psychological stress emerging as a key concern. Youth face barriers in translating educational aspirations into sustainable livelihoods, emphasizing the need for inclusive resilience-building interventions. Together, these results demonstrate the need for a gender-sensitive approach to resilience that emphasizes local constructs of adaptive capacity and the need to support relational forms of resilience in ways that bridge social, ecological, and cultural systems.

Introduction

Pastoralism supports millions of livelihoods in Africa, contributing 40% to agricultural GDP (Glatzel et al., 2020). However, pastoral systems in African drylands, particularly in the Horn of Africa, face increasing vulnerability due to climate change (Godde et al., 2020). Repeated droughts, including the recent five consecutive rainfall failures in the Horn, have devastated water and forage availability, threatening the food security of 54 million people despite significant investments in resilience-building programs (GCA, 2024; WorldBank, 2022).

Gender plays a significant yet underexplored role in how resilience is constructed in these contexts. While men typically manage herding and mobility, women assume vital roles in domestic management and economic activities (Flintan, 2008; Hodgson, 1999). As a result, the current literature has identified that women's vulnerability is increased and that women have limited capacity to adapt to climate change (Grillos, 2018; Walker et al., 2022). As Semplici and Campbell (2023) highlight, framing pastoralists as inherently vulnerable leads to an oversight in which pastoralists are assumed as lacking adaptive capacity, without examining how they respond during crises and ultimately overlooking dynamic adaptation.This study explores how gender influences resilience strategies among pastoralist communities in Northern Kenya, emphasizing the importance of nuanced, gender-sensitive resilience-building approaches using a theoretical framework based on relational resilience (Reyers et al., 2022). By recognising the agency of pastoralists, this study aims to explore how gender influences local resilience strategies in pastoralist communities in the Horn of Africa, contributing to a more nuanced understanding of resilience that will inform gender-responsive policies and development programming.

Methods

This study took place in six villages in Moyale, Marsabit County, Kenya, representing varying degrees of market integration and development (Figure 1). Data collection, conducted from January to February 2024, included 39 semi-structured interviews and focus group discussions with pastoralists, government representatives, NGOs, and researchers (Table 1). A pairwise ranking exercise was used during focus groups to understand the relative importance of gender and other actors in resilience strategies.

Table 1: Characteristics and research activities at study locations. Focus group discussions (FGD), key informant interviews (KII).

Location	*Population Size*	*No. of FGD (women)*	*No. of KII (women)*	*No. of FGD (men)*	*No. of KII (men)*	*No. of FGD (youth)*
Sololo		0	2	0	0	0
Madoadi		1	1	1	3	1
Walda		1	3	1	3	1
Bori		1	1	1	1	0
Amballo		1	1	1	1	0
Adadi		1	3	1	3	1
Total		**5**	**11**	**5**	**11**	**3**

Transcriptions were thematically analysed using Dedoose software to extract insights into gendered resilience pathways. Focus was placed on strategies such as diversification, destocking, mobility, and fodder management, with special attention to the evolving roles of men and women during drought crises.

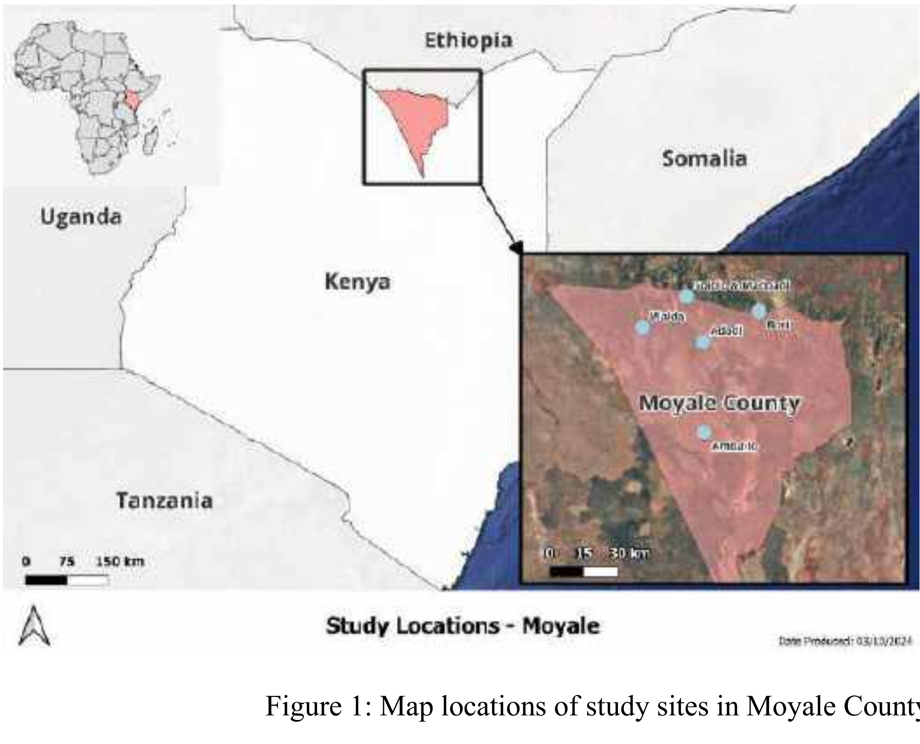

Figure 1: Map locations of study sites in Moyale County, Kenya.

Results

Resilience Pathways and Gender

Pastoralist resilience strategies during drought are multifaceted, with gender playing a central role in shaping both actions and outcomes. These strategies reflect the dynamic nature of pastoral adaptation and the evolving roles of men and women in responding to crises.

Small scale crop farming

Small scale crop farming has become an emerging resilience strategy for pastoralists, focusing on fodder cultivation or growing maize for livestock and human use. However, environmental challenges such as erratic rainfall and poor soil limit its viability. In some cases, poorly maintained infrastructure, like failed irrigation systems, exacerbates these difficulties. A participant from Madoadi noted, "Our land is fertile and has good soil, but the problem is that we don't have much education on it, and also the climate is not constant." Women often bear additional burdens in small scale crop farming, facing increased labour demands without sufficient training or support. Additionally, without external investments in education and infrastructure, crop farming often results in maladaptation.

Diversification

Both men and women have adopted diversification into non-livestock income streams, but women tend to drive this trend, especially during times of crisis. Women in locations like Walda, where infrastructure exists, have successfully engaged in camel milk trading, empowering them economically and enhancing their household resilience. Pastoral communities have also diversified their livestock to include a higher proportion of drought resilient species such as goats and camels to complement cattle.

While diversification can complement traditional livelihoods (McCabe, 2010), many pastoralists view it as a temporary survival strategy rather than a sustainable solution. One woman from Adadi reflected, "We didn't even know that we were rich. It was only after the animals started dying... that we realized how many cows we had." This sentiment underscores the cultural and economic centrality of livestock, highlighting the emotional toll of diversifying away from pastoralism.

Women's and Community Groups

Women-led community groups play a vital role in resilience by pooling resources, offering financial support, and fostering solidarity during crises. These groups engage in diverse activities, such as brick-making and fodder production, while also serving as emotional support networks.

The impact of these groups extends beyond economic resilience, promoting social cohesion and enabling members to navigate the psychological challenges of drought. Men also acknowledged the importance of these groups, with one participant stating, "After the loss of the livestock, we had no other things to depend on unless the women's groups sustained the family."

Mobility

Mobility remains a cornerstone of pastoral resilience, allowing herds to access grazing lands and water. Pastoralists expressed concern that areas they had traditionally relied on for pasture and water were also suffering from repeated failed rainy seasons. One man from a focus group discussion in Walda said, "When the drought comes, we used to run away with livestock to other parts but when there is drought everywhere, that is when we lose all our animals when it reaches that point, we call onto government for help". This research revealed the emergence of new mobility practices, such as using trucks to transport animals over greater distances. However, this option remains accessible only to a select few pastoralists with surplus income, often derived from educated family members working outside traditional pastoralism.

Decisions regarding livestock movement are typically made at the family or village level but are predominantly led by men, reflecting the entrenched tradition of male ownership of livestock (Flintan, 2008). During a focus group discussion with women in Madoadi, one woman expressed that, "All decisions are made by fathers. If there could be involvement of women and maybe children or a family member, we would have not lost all this livestock.” Fostering greater involvement of both men and women in mobility-related discussions and decision-making processes can provide valuable perspectives and contribute to more equitable outcomes.

Destocking
Destocking of the herd emerged as a crucial practice aimed at supporting remaining livestock and acquiring feedstuff for humans. This study found that decision-making surrounding destocking was predominantly led by men, reinforcing the prevailing sentiment from interviews that livestock ownership is traditionally associated with men. It was often not until later in the drought, when animal condition deteriorated and resources became scarce, that animals were sold, typically at a minimal ‘giveaway’ price. These findings highlight destocking as a gendered resilience strategy that necessitates more inclusive dialogues and reflective practices to enhance decision-making processes for better future outcomes.

Buying Fodder
Purchasing fodder is an emerging strategy, often funded through partial destocking or community savings. Many pastoralists bought fodder for the first time during the recent drought, underscoring their adaptability. However, challenges around pricing and quality remain significant. One participant described the fodder as “Poor, because it was just for business,” while another added, “We bought it because we didn’t have other options.”

Both men and women participate in fodder buying, reflecting evolving gender roles. Streamlining this practice through improved quality control and support for local fodder production could enhance its effectiveness as a resilience strategy.

Collecting Fodder
Collecting branches and twigs for livestock feed is predominantly a women-led activity. This physically demanding task often becomes a last-resort strategy during severe droughts, with women expressing frustration over men’s disengagement. One woman from Sololo noted, “Men sit idle, chewing mirra (khat), while we search for fodder.”

This dynamic highlights the gendered burden of resilience strategies, as women shoulder the dual responsibilities of livestock care and household management. Addressing these inequities through targeted support and training could alleviate the strain on women while enhancing overall resilience.

Cooking Human Food for Livestock
During extreme scarcity, women prepare human food such as maize or boiled feed for livestock, prioritizing herd survival over their own nutrition. This practice underscores women’s adaptability and commitment to maintaining livestock health. However, it also reflects the dire circumstances faced by pastoral families, emphasizing the need for timely interventions to prevent such drastic measures.

Humanitarian Aid
Humanitarian aid, particularly cash transfers, plays a pivotal role in supporting pastoralist households during crises. Women, who are often the recipients of these transfers, effectively manage the funds to meet immediate needs. The fact that women predominantly managed cash transfers reinforces their role as key actors in maintaining household resilience, underscoring their capacity to stretch limited resources in ways that ensure the family's immediate needs are met. One participant remarked, “The money helped us buy food and water for the children.”

However, delays in aid delivery often limit its impact. A pastoralist lamented, “If only they held our hand while we still had strength.” While essential for short-term survival, aid must be complemented by long-term strategies that reduce dependence and enhance local resilience.

Pairwise Ranking

Pairwise ranking exercises revealed that women are consistently viewed as the most critical actors during crises, followed by men, NGOs, youth, and the government. Women's central role in managing household resources, community groups, and resilience strategies underscores their importance in crisis response. A participant from Bori summarized, "Women are the ones who keep families alive when the animals are gone."

Discussion

While both men and women contribute to resilience-building in pastoralist communities, the roles they assume are shaped by deeply ingrained gender norms. Women often take the lead in household management, resource allocation, and community support, particularly during times of crisis. Participants from both gender groups acknowledged that women are central in efficiently managing available resources, including money, food, water, and livestock through fodder collection and the preparation of human food for animals. Their multifaceted role reflects broader literature that positions women not only as primary caretakers of their families but also as key contributors to the community's well-being during hardship (Flintan, 2011; Huyer et al., 2024).

These findings challenge the dominant narrative in some of the resilience literature, which portrays women in pastoral communities as the least resilient due to increased vulnerability and reduced adaptive capacity (Huyer et al., 2024). Contrary to this perspective, women emerge as key actors in sustaining lives during shocks, particularly through short-term household resilience strategies. This calls for a rethinking of gendered assumptions in resilience studies and underscores the importance of strengthening the pathways women use to support households, such as community savings groups, diversification activities, and water management practices. However, resilience-building programs must also address socio-cultural barriers that limit women's involvement in broader decision-making processes.

Rather than focusing on access to capital assets and income, such a perspective on resilience emphasizes the social, relational roles that women play in supporting households, often as part of collective efforts, both with men but also particularly other women. These efforts align with the concept of relational resilience, emphasizing the dynamic interconnections between social, ecological, and household systems. Women's expertise in navigating uncertainties and complex socio-ecological systems positions them as pivotal actors in both immediate and long-term responses to shocks. The capacity of women, rather than their associated capital, and their ability to draw on relational networks therefore emerged during this study as important factors for ensuring resilience through drought, across the activities. These findings align with wider perspectives on resilience theory explored by Reyers et al. (2022) and the highlighting of relational resilience as central in pastoral systems (Konaka et al., 2024; West et al., 2024).

As droughts intensify in the context of climate change, gendered roles become more fluid. Women increasingly take on additional responsibilities, while men face new psychological and emotional challenges. Studies indicate that men's traditional roles in pastoralist communities, particularly in livestock herding and mobility, are increasingly undermined by climate-related shocks (Hanigan & Chaston, 2022). This disruption often leads to heightened psychological stress, with some men turning to distractions like mirra (khat), contributing to disengagement as livestock losses mount (McPeak & Little, 2019). This study echoed these findings with substance use reported among men highlighting the need for mental health interventions that are culturally sensitive and embedded within existing community structures. Addressing men's mental health is crucial not only for their well-being but also for maintaining their active role in long-term resilience strategies, particularly in adapting livestock management to changing conditions through mobility and livestock care.

Meanwhile in terms of external support through 'resilience' programs, even though overall they were ranked low, some NGOs were acknowledged for their life-saving interventions, even though pastoralists expressed frustration over the delayed arrival of aid, a critique echoed in other studies that document the lag in humanitarian responses in pastoral areas (Fitzpatrick, 2024). The government was ranked as the least essential actor, often seen as offering minimal and delayed support, reinforcing findings on the lack of timely state intervention in pastoral regions.

Furthermore, the shifting dynamics observed during the depths of drought suggest a broader evolution in gender roles (Karmebäck et al., 2015). As men become increasingly dependent on women for household survival during crises, this dependence has the potential to reshape gender relations beyond the immediate crisis period. There is a need for more longitudinal research that tracks how gendered resilience strategies evolve over time in response to recurring shocks (Bryan et al., 2023; Juran & Trivedi, 2015). While much of the existing research focuses on short-term responses to crises such as drought, little is known about how men's and women's roles in resilience change across multiple cycles of shock and recovery. This could offer insights into the sustainability of certain strategies and whether they are becoming more or less gender-inclusive over time.

To foster holistic, gender-sensitive resilience, interventions must address socio-cultural barriers limiting women's involvement in decision-making while equipping men with the mental health and adaptive capacity-building support needed for sustainable livestock management. Aligning with relational resilience, which emphasizes context-sensitive, adaptive strategies rooted in local knowledge, such efforts can better navigate the uncertainty characteristic of pastoralist systems.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Unleashing multifunctionality: How policy support and good governance are key to sustainable land management.

Haddad, F; Chnais, E.

Food and Agriculture Organization of the United Nations.

Keywords: Silvopastoralism, dryland forests, policy reform, participatory processes, sustainable land management

Abstract

This paper examines how policy and legal frameworks in Morocco and Lebanon are evolving to promote sustainable silvopastoralism in dryland forests. In Morocco, a participatory approach led to the development of a national silvopastoral strategy in 2016, building on earlier initiatives that offered financial incentives to communities for protecting reforestation sites. This approach has resulted in improved forest restoration, better livestock management, and socioeconomic benefits for local communities. Lebanon, facing challenges posed by its outdated Forestry Code, initiated a comprehensive review process in 2015 with support from the Food and Agriculture Organization of the United Nations (FAO). Alongside the development of a national agricultural strategy and rangeland management guidelines, this process aims to modernize forest and rangeland governance, promote community engagement, and ensure the sustainable use of natural resources. Both case studies highlight the importance of adaptive policy frameworks, stakeholder collaboration, and community engagement in achieving sustainable forest and rangeland management in dryland ecosystems.

Introduction

Rangelands play a crucial role in rural development by producing goods and ecosystem services, including supporting, provisioning, regulating, and cultural services. In several middle eastern countries, dryland forests and silvopastoral systems are vital for the livelihoods of rural communities, significantly contributing to national livestock production. However, forest and rangeland policies often consider pastoralism and pastoralist communities as a driver of degradation, favouring afforestation and reforestation policies that marginalize pastoralists instead of considering silvopastoralism as a true asset for enhanced ecosystem management. This paper examines how an enabling environment, brought on through enhanced policies and legal instruments, is helping to restore and sustain the pastoral areas in Morocco and Lebanon.

Towards enabling policies

In Morocco, customary laws permit people living near forests to graze their livestock within forest domains, making silvopastoralism an integral part of the ecosystem. However, socioeconomic changes and environmental factors have led to overgrazing, threatening the sustainability of these ecosystems (Moukrim et al., 2019). To address these challenges, the Forestry Department developed a national silvopastoral strategy in 2016 aimed at restoring and sustainably managing forest resources. The strategy emerged as a response to the pressing issue of overgrazing in dryland forests, which contributes to vegetation loss, land degradation, and soil erosion. The strategy, developed through a participatory approach, represents a legal instrument to achieve sustainable forest management by addressing ecological, social, and economic factors. The strategy focuses on long-term restoration and sustainable management of silvopastoral resources through good governance, ensuring socioeconomic well-being of the population, biodiversity conservation, and climate change mitigation. The development process involved five key phases: 1) ***Diagnosis*:** A silvopastoral diagnosis of existing conditions and challenges was conducted; 2) ***Capacity building:*** Strategic planning capacity was built among stakeholders to ensure institutional anchoring; 3) ***Interactive workshops:*** Workshops with partners and civil society facilitated strategy formulation; 4) ***Sharing workshop results:*** Results from workshops were shared with managers to ensure a uniform understanding of the strategy's direction; and, 5) ***Formulation and restitution:*** The strategy was formulated and presented in a simplified format to ensure visibility and readability (FAO, 2022).

This strategy builds on Morocco's previous policies to support pastoralists. In 2002, the government initiated a compensation programme for forest areas closed to grazing. This sought to facilitate long-lasting and viable solutions, reduce the heavy grazing pressure on forest ecosystems, and support reforestation initiatives. Financial incentives were offered to forest users organized into grazing associations, provided they adhered to grazing restrictions in designated reforestation sites. These communities were made responsible for protecting their lands and organizing grazing schedules to prevent overgrazing and allow the land to recover (FAO, 2022).

In Lebanon, the Forestry Code of 1949 has been the cornerstone of forest management in the country. It grants the Ministry of Agriculture (MoA) authority over the use, protection, and management of forest resources. However, the 1949 Forestry Code faced increased fragmentation, lack of clarity on rangeland management and insufficient community engagement. Recognizing these limitations, the Lebanese government, with support from FAO, undertook efforts to enhance forest and rangeland management policies. Since 2015, the MoA and FAO have collaborated ***to review and amend the Forestry Code***. The review process was divided into three phases: 1) Detailed review of the existing forest code to identify its strengths and weaknesses; 2) Consultations with a wide range of stakeholders, including government agencies, NGOs, and the private sector to gather feedback on the proposed revisions to the forestry code; and, 3) Drafting of the revised forestry code, integrating the feedback from the consultations. Regarding rangeland and silvopastoralism, the revised law aimed to address the specific challenges of rangeland management, regulate grazing practices, promote sustainable livestock production, and minimize conflicts between pastoralists and other stakeholders (FAO, 2024). In addition to the review of the forestry code, the Ministry of Agriculture developed the ***Agricultural Strategy*** (2020 - 2025), which emphasizes the importance of community engagement and sustainable management of rangelands, within and outside forests. This strategy aims to improve food security and the livelihoods of pastoral communities, promote climate change adaptation, and ensure the sustainable use of natural resources (MoA, 2020). Furthermore, in 2018-2019, the UNDP, through its project "Sustainable Management of the Qaroun Watershed", developed ***National Guidelines for the Management of Rangelands*** within and outside of forests.

Preliminary **positive changes**

The Moroccan Forest Department realized the importance of piloting initiatives to ensure the effective implementation of the strategy and evaluate its effectiveness. This led to the development of a regional silvopastoral strategy and a territorialized action plan, involving communities and stakeholders to ensure adaptation to local contexts and climate change considerations. The regional plans aimed to enhance silvopastoral ecosystems, improve the organization of pastoralists, support socioeconomic development of areas, improve the governance of resources, and promote holistic research (FAO, 2022).

The number of grazing associations and their members participating in the incentives programme has steadily increased. By 2019, more than 175 beneficiary associations were managing over 101 000 hectares of dryland forests. This growth in grazing associations has been directly linked to improved reforestation success rates and a significant reduction in grazing offences. A fundamental aspect of the programme's success is its participatory approach. Stakeholders embraced community involvement in forest resource management, and local communities agreed that this mechanism had improved collaboration with the forest administration. The policy changes, co-created with local communities and pastoralist groups, have resulted in better livestock management, effective forest restoration, enhanced land and forest management, and economic and environmental benefits for all involved.

Despite the challenging economic and security conditions Lebanon has faced in recent years, the country successfully completed the revision of its Forestry Code and submitted the revised law for official endorsement by the Council of Ministers. This revised law is a major national milestone that will provide a solid foundation for the sustainable management of Lebanon's forests and rangelands while improving the livelihoods of the people that depend on them (FAO, personal communication). The Agricultural Strategy, which integrates rangeland priorities, has increased national interest in rangeland management and encouraged more local actors and development agencies to integrate rangeland management within their strategies. Additionally, the National Guidelines for Rangeland Management were applied in a pioneering project implemented by FAO, in collaboration with the MoA, to prepare a comprehensive management plan for the Tannourine community in North Lebanon, balancing environmental conservation with social needs.

Discussion

Policy reform is essential for advancing rangeland management and recognizing pastoralist communities' rights to access and benefit from range resources. Policy bottlenecks have been identified as significant barriers to effective rangeland management in various parts of the world. Misunderstanding of pastoralist communities has resulted in policies that harm rather than help these communities. This outdated view creates tension, marginalization, and instability within pastoral communities (Nori and Scoones, 2023). The process Morocco followed to update its policy framework reflects the importance of formulating adaptive, locally contextualized strategies that incorporate the latest scientific advancements (Dong et al., 2016). Moreover, financial incentives, when implemented correctly, can significantly increase the adoption of sustainable practices. Evidence suggests that these incentives are a more effective alternative to state subsidies for fodder purchases and barley cultivation (Louhaichi et al., 2016).

Conclusion

Effective management of silvopastoral systems is essential for preserving the ecological integrity and socioeconomic well-being of Morocco and Lebanon. Ongoing efforts to enhance policies and legal frameworks highlight the importance of a shared vision and collaborative effort among stakeholders. Further, they provide a crucial opportunity to address existing challenges and promote sustainable forest and rangeland management practices. Successful implementation depends on fostering community engagement and strengthening the capacity of stakeholders. Continuous monitoring, evaluation, and adaptive management will be crucial to ensure an enabling framework for the sustainable management of Morocco and Lebanon's valuable dryland forests and rangeland ecosystems.

Bridging gender gaps in rangeland resource and conflict mapping: the role of participatory GIS, a case study in Kenya

Paliwal, A[1]; Korir, V.K [2]; Kenduiywo, B[2], Galie; A, [1], Bullock, R[1]; Pacillo, G[3]; Wane, A[4]; and Whitbread, A[5]

[1]International Livestock Research Institute, Nairobi, Kenya; [2]Alliance-Bioversity-CIAT, Nairobi, Kenya; [3]Alliance-Bioversity-CIAT, Rome, Italy; [4]International Livestock Research Institute, Dakar, Senegal [5]International Livestock Research Institute, Dar es Salaam, Tanzania

Key words: Participatory GIS (PGIS); Gender Inclusion; Rangeland; Resource Mapping

Abstract

This study examines the role of Participatory Geographic Information Systems (PGIS) in resource mapping, policy formulation, and conflict resolution in Isiolo County, Kenya. PGIS integrates Traditional Ecological Knowledge (TEK) with modern mapping to engage local communities and enhance mapping accuracy beyond conventional methods. The approach emphasizes gender inclusion, as men and women contribute distinct yet complementary knowledge. Men typically identify broader geographic features and economic stability resources, while women provide insights into water sources and household-level needs, addressing issues such as water access and food security. Gender-specific maps underscore the value of including women in resource management, fostering strategies that reflect the needs of all community members and enhancing decision-making equity. PGIS also helps address regional conflicts over rangeland resources by mapping contested areas and facilitating dialogue among groups like the Samburu and Turkana communities. Through Focus Group Discussions (FGDs) and Key Informant Interviews (KIIs), the study captures a wide range of local perspectives on environmental challenges, climate impacts, and security risks. This inclusive approach supports culturally relevant and scientifically grounded resource governance, which is essential for building resilience in pastoralist communities. Overall, the findings highlight PGIS as a valuable tool for sustainable rangeland management, aligning with broader frameworks for climate resilience and conflict management. By promoting community-led mapping and incorporating diverse perspectives, PGIS enables comprehensive solutions to complex environmental and socio-economic challenges, advancing effective policy outcomes in Kenya's rangelands.

Introduction

Rangelands, often arid or semi-arid landscapes, are essential for millions of pastoralists and agro-pastoralists who rely on grazing lands, water sources, and vegetation for their livelihoods. However, these resources are highly variable and vulnerable to environmental pressures. Participatory Geographic Information Systems (PGIS) is a valuable tool in Africa for managing these rangelands (Cho and Mutanga 2021). PGIS combines traditional ecological knowledge with modern mapping technologies, allowing local communities to contribute their understanding of the landscape to create accurate, context-specific maps that often surpass what remote sensing alone can achieve (McCall and Dunn 2012). Incorporating gender balance in Participatory GIS (PGIS) is essential because men and women bring distinct knowledge and experiences regarding natural resources. Including both perspectives ensures comprehensive, accurate resource mapping and supports equitable decision-making (Bullock et al. 2022). Actively involving women in PGIS recognizes their specific needs, like water accessibility, fostering solutions that benefit all community members (Boongaling et al. 2023). This inclusivity also boosts community buy-in, as both genders see their input reflected in management plans, creating shared ownership crucial for sustainable resource initiatives.

Our study examines community perceptions on land use, natural and market resources, land management challenges, and climate-related risks, recognizing the often-gendered nature of these views. We used PGIS, focus group discussions, and key informant interviews to capture gender-specific local knowledge for more accurate rangeland mapping. Key objectives include integrating traditional ecological knowledge into PGIS, engaging diverse community members—especially women and marginalized groups—to ensure comprehensive resource management, and using PGIS to map conflict zones, promoting dialogue and cooperation to resolve disputes.

Methods

We conducted a Participatory GIS (PGIS) workshop in Isiolo County, Kenya, to gather local insights on rangeland resource management in May 2024. Participants were divided into three groups—men, women, and a mixed group (both men and women). Each group was supported by an enumerator trained in map reading and effective questioning. The male and female groups were facilitated by male and female enumerators, respectively, to ensure comfortable and open discussions. Each group received a paper map created from Google Earth images (scale 1:22,000) of western Isiolo, consisting of seven joined A1-sized sheets (Corbett 2009). Participants mapped natural and market resources, livestock migration routes, water sources, overgrazed and underutilized areas, and conflict zones (Figure 1).

Figure 1. Different groups at doing a mapping exercise. The right panel shows the map after exercise was conducted

In addition to mapping, we held focus group discussions (FGDs) with all three groups. These discussions aimed to deepen our understanding of the participants' perspectives on local geography, resource utilization, environmental and land management challenges, service access, climate impacts, conflict zones, and security risks. To further validate and expand on the FGDs and mapping results, we conducted key informant interviews (KIIs) with local experts.

Our data analysis involved multiple steps: initially, participants identified and marked familiar features on the map. FGD transcripts were organized and coded based on recurring themes, including land use, resource ownership, climate stressors, and conflict dynamics. Using Nvivo software, we performed thematic analysis to explore patterns across the groups, paying particular attention to gender-based differences in perceptions. This comparative approach helped reveal how men, women, and mixed groups experienced and prioritized rangeland issues differently, enriching our overall understanding of resource management challenges in Isiolo County.

Results

Gendered Perspectives on Resource Mapping

Incorporating gendered perspectives in Participatory GIS (PGIS) exercises has highlighted the distinct yet complementary contributions of men and women to resource mapping in pastoralist communities. The differences in how men and women valued and utilized rangelands were evident in their contributions. Men, often engaged in broader community-level resource management, were quick to map livestock routes, conflict-prone areas, and critical grazing lands, emphasizing practices that sustain herds and support economic stability. Women, initially hesitant, contributed detailed insights into household-level resource needs once engaged. They mapped essential water sources and seasonal rivers, underscoring the critical impact of water scarcity on daily routines and food security. In the mixed group, these perspectives merged, creating a holistic view of rangeland resources (Figure 2). This integration showcased the value of both men's ecological knowledge and women's focus on resource availability for household and livestock needs, emphasizing that inclusive mapping fosters a comprehensive understanding of resource use and challenges.

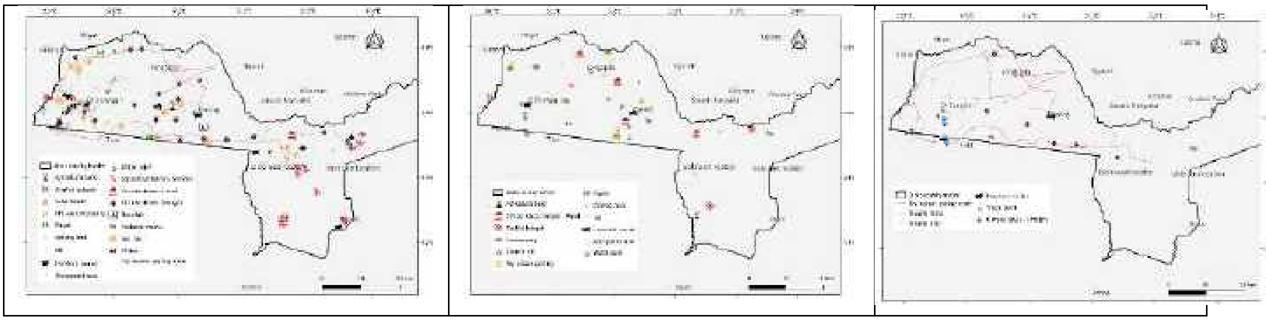

Figure 2. Features marked by men, mixed (both men and women) and women group

Gendered Roles in Environmental Resilience and Conflict Management

The FGDs provided deeper insights on how gendered perspectives shape responses to land challenges, climate stressors, resource conflicts, and climate-related security risks (Figure 3). Men focus on grazing boundaries, livestock disease management, and constructing gabions to prevent soil erosion, while women manage household water resources, build soil conservation structures, and plant grass to protect soil. Climate change exacerbates these challenges, with men noting issues like livestock diseases and resource loss, and women facing heightened burdens in household care and food security due to water scarcity. Conflicts over grazing lands and water points also reveal gendered impacts, with men often involved in cattle rustling disputes and women facing increased vulnerability when managing household survival after conflict. Community-driven solutions, like peace committees and local agreements, demonstrate the need for inclusive, culturally grounded strategies that integrate both men's and women's knowledge for effective resource management and conflict resolution.

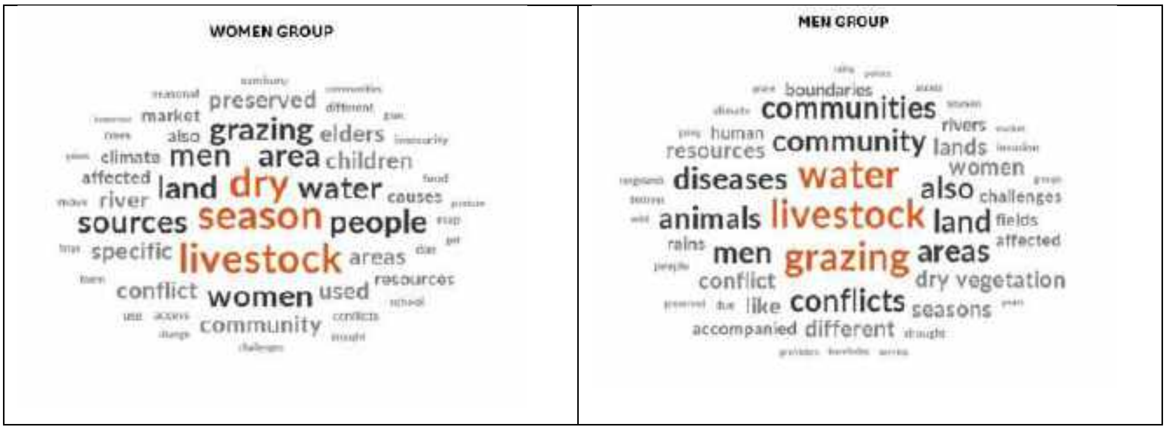

Figure 3. Comparative word clouds highlighting key concerns of women and men groups in Isiolo county, Kenya on resource management and environmental challenges.

Discussion and Conclusions

Our study demonstrates the effectiveness of Participatory GIS (PGIS) for resource management and policy formulation by promoting inclusive decision-making. In our study, we prioritized the inclusion of diverse community members, particularly women and marginalized groups, to capture a wide range of knowledge and experiences related to resource management. The findings revealed that while women provided valuable insights on water points and grazing lands, they lacked confidence in addressing topics like agrovet locations and climatic stress points, often highlighted by men. This reflects women's historical exclusion from resource management discussions, which has limited their exposure and capacity to communicate on these platforms. Gender-specific maps created in our study underscore the unique insights that women bring, especially in areas like water access and household resource use, making them essential for comprehensive management plans. Comparing responses from men, women, and mixed groups provided a deeper understanding of local geography, resource use, and environmental challenges. In conclusion, our research underscores the importance of PGIS, community engagement, and gender inclusion in managing Isiolo's resources. Furthermore, PGIS fosters greater community engagement in policy development, ensuring that policies are grounded in local realities and supported by the people they impact. This engagement helps build trust (McCall 2021).

Abstract
Rangeland soils in Australia are diverse and integral to the country's vast arid and semi-arid landscapes, covering approximately 75% of the continent (DAFF 2024). These soils are typically shallow, often but not always nutrient-poor, and have low organic matter due to the region's low rainfall, high evaporation rates, and sparse vegetation. Rangeland soils are commonly prone to erosion and salinity, especially when vegetation cover is disturbed. Despite their limitations, these soils support unique ecosystems and are used for extensive grazing, playing a critical role in Australia's agricultural and ecological systems. Sustainable management practices are essential to maintain their productivity and prevent degradation. Education, training, and support for pastoral land managers in the soil sciences is pivotal to protecting and enhancing rangelands systems, especially given the frequency and intensity of rainfall events that are predicted with future climatic variability. Shifting the focus of rangelands management back to the fundamentals of understanding soils from a whole of landscape perspective and adopting a "from the ground up" approach to pastoral productivity is re-empowering a new generation of pastoral land managers with knowledge and confidence to adopt regenerative land management tools.

Introduction
The South Australian Arid Lands (SAAL) Landscape Board region covers over **400,000 square kilometres**, making up more than half of South Australia (SAAL 2024). Characterized by expansive plains, low-lying scrublands, and distinctive ecosystems adapted to harsh conditions, including hot dry summers and cold winters, this vast area includes some of the driest climate zones and most ecologically significant landscapes in the state. Despite the challenging environment, the southern rangelands are rich in biodiversity and offer opportunity for productive grazing systems.

Comprehensive soil testing across rangelands regions can be expensive and, outside of crop production systems in more reliable rainfall regions, have largely been an uncommon practice. There are very little agronomic inputs or interventions that can be administered to rangelands soils to alter soil chemistry or initiate soil structural change in a cost-effective manner, and for this reason it is uncommon for intensive testing or review of soils to have been undertaken. However, rangeland managers can learn and derive value from agronomic and environmental soil testing practices and other areas of formal soil science. This paper highlights the importance of understanding soil fundamentals to make more informed and effective land management decisions through exploration of datasets and techniques employed to engage pastoral land managers in the process of understanding rangelands soils.

Methods

The project has involved the design, implementation and delivery of extension programs focussing on collecting and analysing soil data from southern rangelands regions of Australia. This involved collaborating with land owners, pastoral station managers, Government and non-government organisations and experts aligned with advising or supporting the implementation of on-ground soils focussed trials or training opportunities in the SA Arid Lands region. The program also reviewed data that was collected from complementary field trials and soil sampling work funded outside of the original projects funded scope.

Soil Sampling

This project enabled the construction of a contemporary soils data set from the SA rangelands region and a total of 200 samples were analysed and reviewed with 175 samples having comprehensive laboratory analysis conducted (SAAL 2024). Soil testing parameters also included measuring soil temperature, biological activity and infiltration rates in the field with land managers. Laboratory results were independently analysed to consider:

- Typical ranges of Soil Organic Carbon across the SA pastoral zone (and causes of outliers)
- Characteristics of southern rangeland soils (chemical & physical traits) that influence the ability to manage regeneration of degraded grazing land
- The potential of different soil types to regenerate, and where to focus management efforts to gain the best outcomes
- Influence of soil health on pasture growth and livestock production parameters

Demonstration sites

In addition to testing soil samples from a range of land systems and rainfall zones, sites of specific interest to pastoral land managers were also tested. Results were used to show case the influence of land management techniques on soil health at demonstration sites on commercial-scale pastoral and rangeland properties, enabling the construction of a soils data set from a total of 21 pastoral leases across the SA Arid lands region. The data has been showcased at field days, demonstration sites, in project communications and on social media channels.

Previous research has shown that engaging land manager participation in scientific research is integral to raising awareness, building knowledge and leading to practice change (Pino et al 2022). At nearly all sites, data was collected with and alongside pastoral land managers. Where possible, qualified soil scientists were engaged to attend field visits. Collaboration with soil scientists and extension personnel with backgrounds in intensive agriculture and broadacre cropping allowed for the application of a broad scope of skills, technologies and backgrounds outside of the normal scope of rangelands ecology. The cross-sector collaboration proved invaluable to further investigating data sets and improving understanding of soil chemical processes and plant growth responses when analysing laboratory data and visiting sites to consider soil property constraints by bringing a different lens to the approach.

Where possible, samples were taken at paired sites, using fence line or track boundaries where areas with identical soil type and rainfall could be compared. Comparisons of soil sample sets at sites where rehabilitation techniques (including water slowing techniques, brush packing to increase rainfall infiltration or differences in grazing management) were undertaken to measure the range and differences of soil properties caused by management inputs or techniques.

Extension activities and land manager engagement

A range of extension tools and facilitation techniques were employed to engage land managers in understanding local rangelands soils through a variety of workshops and field day events. All events were designed to provide as much practical, "hands-on" learning as possible. Design and delivery of field trips, tours and training days took participant experience and demographic background into account. Adult learning styles were considered carefully during event design, with special attention given to constructing activities and content delivery to focus on kinaesthetic, interpersonal learning types using varied instructional methods (Burns, 1995).

Out-of-classroom demonstrations were employed as much as possible, encouraging the group to collect data and measure soil properties in the paddock. These soil properties included measurement of pH, salinity, soil texture and colour, water infiltration rates and soil temperature. To create engaging dialogue, a fundamental soil property principle was described (for example, the influence of soil organic matter on soil structure) then participants were asked to estimate the measure or impact of an application of management inputs to the concept and collect data in teams. By engaging small groups to apply the experiment or collect data, a competitive element was added to increase engagement from the group. This form of engagement works well with pastoral audiences. Retention of knowledge and learnings about soil properties was enhanced by paying special attention to participants response and engagement and allowing flexibility to change demonstration approaches if needed.

Soil biological indicator trends were monitored using the 'Soil Your Undies' technique (DeBruyn 2018). Cotton underpants were buried at demonstration sites up to two months in advance of field days at the site. Participants were asked to uncover the buried material and share observations with the group. Cotton underpants were consistently more degraded in healthier soil patches (aligned with higher Organic Carbon (OC) and perennial plant cover) at all paired trial sites. As soil biology is expensive and difficult to measure with laboratory sampling methods, this form of experiment was a powerful and cost-effective tool, using a novel approach to educate land managers, integrating visual interactive assessment, humour and science.

Results

Numerous soil parameters were measured from laboratory test sets (SAAL 2024), for the purposes of this paper, data analysis will focus on a sub-set of parameters of interest to pastoral land managers.

Soil Organic Carbon

Organic Carbon (OC) is influenced by climate, soil type and management. The SAAL region has challenges around all three of these factors. The OC levels (Walkley and Black) from soils tested ranged from 0.25% to 1.5% with some outliers up at 2 to 2.5% OC. The average OC% was 0.58% and half of the samples were below 0.45% OC. The level of detection for OC% as a Walkley & Black analysis is 0.25%.

Building soil carbon in rangelands soils is complex and largely dependent on climatic variables and soil types, however data collected from paired treatment sites across the project footprint suggest that soil conservation practices and rest-based grazing management can have a significant impact on soil carbon stores at scale.

Soil Salinity

Salt content of the top 10cm of soil profiles across the pastoral soils data set, measured as Electrical Conductivity ECe, ranged from 0.15 to 32dS/m (with an outlier in salt lake country reaching 55dS/m). All areas in the southern rangelands need to be managed to address the salt accumulation potential at the soil surface, which can lead to scalding, plant species decline and reduced pasture growth. The data sets at paired sites consistently demonstrated that improving soil water infiltration, and maintaining soil cover reduces salt accumulation in topsoils, which is critical for seed germination and seedling establishment.

Soil water infiltration and surface temperature

Opportunistic testing of soil surface temperatures along transects with different vegetation cover parameters were particularly impactful in group training exercises during paddock walks. Using a digital infrared thermometer, participants were asked to monitor and record soil surface temperatures with and without perennial plant cover. The presence of large perennial shrubs and ground cover influenced soil surface temperatures by up to 32 degrees Celsius – being the difference between extremes in soil surface temperature recorded across a short gradient. Participatory data collection in 'real-time' enabled strengthened learning outcomes. The same approach was made with testing differences in simulated rainfall infiltration experiments (NQ Dry Tropics 2019). Differences in soil water infiltration times ranged significantly according to soil type, with the most significant differences being measured in paired treatments sites that had undergone mechanical intervention, such as deep ripping.

Project participation

In total, 324 individuals participated in one or more soils focussed field days over the two-year life span of the funded project. This included on-ground field days, training days, a virtual field day and a week-long bus tour into western New South Wales. Of note was the attendance (not captured in attendance data) of more than 55 children to the events. Designing and facilitating inclusive events (families encouraged to attend events) is important in a region where childcare is limited, and all family members are involved with the day-to-day activities of a pastoral business.

The outcomes of a week-long facilitated inter-regional tour with twenty pastoral participants, continues to be monitored. All participants engaged in the learnings have committed to undertaking practice change since returning to their home properties. Participants on the tour alone are collectively responsible for managing 1.8 million hectares of pastoral and grazing lands in South Australia. Follow-up interviews with participants have recorded changes which include transition to changing livestock enterprise make-up, installation of major soil conservation works, successful enrolment in post-graduate study in soil biology and the acquisition of grant funds to undertake large-scale land rehabilitation works.

Discussion

South Australia’s environmental trend and report card published in 2023 states that soil erosion risk in the southern pastoral region of South Australia has been worsening over the last five years (DEW 2023). The report illustrates the impact of dry conditions on soil health and erosion risk, and further strengthens the importance of understanding the fundamental of soil properties through case studies, training and well-designed soil extension programs to support land managers with regard to managing soil health.

In the southern rangelands, especially in pastoral areas where the land area under management is vast, it is often considered that the soil “is what it is” and focus is given to the landscape from a vegetation dominance perspective. Soil analysis within the pastoral industry is generally limited and land managers often lack the context of what the soil data means relative to other areas of the landscape. Supporting pastoralists to adopt strategic soil sampling regimes, and appropriate analysis to target an improved understanding of the soil properties that are driving high and low performing production zones is a critical step forward.

Water and where it goes, defines what grows; Land managers adopting a strong understanding of the soils influence on landscape hydrology and water movement within the soil profile are recognising they have impact and control to redefine soil management in the rangelands, for future productivity and environmental gains.

Acknowledgements

This project was delivered by the SA Arid Lands Landscapes Board with major funding provided by the Drought Resilient Soils and Landscapes program through the Future Drought Fund and has enabled the collection and collation of large amounts of soil health data and associated knowledge from many disciplines involved in rangelands grazing management.

Northern Australian Indigenous producer group progress, learnings and contributions

Perkins, ID[1]; Pascoe, F.[2]; Gorringe, M[3]

[1] LPM QLD; [2] Morr Morr Pastoral Company; [3]Mithaka Aboriginal Corporation

Key words: Indigenous; Two Way; Engagement; Empowerment; Participation

Abstract

This paper tells a story of engagement, respect, learning and hope. Indigenous involvement with the northern cattle industry has been a foundation element since the industry began to operate on indigenous land, over 150 years ago. That involvement has seen many changes and this project represents a change towards improved indigenous engagement with research and extension, with industry movement towards sustainability and with a two-way approach to developing ways to live in this landscape while meeting environmental, social, cultural and financial aspirations. Engagement with elders, time on country, time for yarning combined with a joint exploration of the collection, analysis and use of data, along with listening to experience both in livestock and land management and care have combined to present pathways and tracks to follow.

Indigenous businesses in this context are largely community owned and operate on community held land. Aspirations for the businesses and for the land differ from the conventional Australian cattle enterprise either family run or large corporate agribusinesses. Employment, caring for country, social and cultural access are important drivers for indigenous land owners and business operators. Profit, efficiency, and asset accumulation are some of the major drivers for non-indigenous cattle enterprise operators. All operators however, have in common the requirement and the desire to care for the natural resource, the livestock and the people and to be productive and profitable. The potential has always existed to work together to create and develop appropriate land management and care approaches.

This project is taking important steps towards integrating indigenous and non-indigenous aspirations and providing learnings for the Australian cattle industry as a whole.

Introduction

Indigenous communities and corporations throughout northern Australia own over 5 million hectares, run over 300,000 head of cattle and employ more that 200 people in the cattle industry. The total footprint of the Indigenous Agricultural sector is estimated at 8.1 million hectares and includes land in every state and the Northern Territory (Barnett 2022). The northern indigenous cattle holdings are on par with the large Agribusiness corporations which have been involved in the Australian cattle industry for over 100 years. Indigenous people have been involved in the Northern Pastoral Industry from its beginning in the mid nineteenth century (Duncan-Kemp 1934). This involvement, from the start has engaged men and women and each are recognised as superb stock handlers and managers. (Simone 2016). However, for much of the last 100 years indigenous pastoral workers and businesses have not been engaged with industry research and extension in any meaningful way, nor have indigenous cattle and land owners and managers been involved in development of industry level strategy, policy or direction (Barnett 2022). Research and extension services, originally provided by state governments, now largely provided by industry bodies, universities and private consultants have been readily available and accessible to non-indigenous producers and have shaped many changes throughout the industry. The lack of engagement of indigenous producers and industry participants is apparent at any cattleman's meeting or workshop throughout northern Australia and at any interaction between industry and government. The level of indigenous employment has significantly declined over the past 50 years (Josif 2009). This results in a two-way loss. Indigenous pastoral workers and managers miss opportunities for employment and to engage with developments in research, technology and management and the industry does not have the opportunity to benefit from indigenous knowledge and experience in land management. Indigenous knowledge has a crucial role to play as the industry develops appropriate responses to the challenges it is facing. Engagement with research and extension and with the broader industry by indigenous cattlemen and women, communities and corporations will be crucial for the industry and for indigenous participants.

The Australian cattle industry faces a period of significant change as resource degradation becomes apparent, the impacts of climate change begin to have an effect and the wider world places more responsibility on land managers to ensure practices are sustainable and now, regenerative. The northern beef industry also faces considerable issues of low productivity and low profitability (McCosker 2010, McGowan 2017). Industry research in 2020 concluded that "poor adoption of production technologies or practice change on farm has been a long standing industry issue" (Fitzpatrick 2020 p. 6.). The Northern Beef Breeding Project was initiated with the aim of addressing the issues of productivity and practice change. The project aims to use peer to peer learning techniques to "engage northern beef producers in the use of objective data to inform business decisions and provide a direct conduit for research and development outcomes to changes in business practice" (Fitzpatrick 2020 p. 3.). This project has taken important steps to encourage, enable and facilitate indigenous participation and two-way learning.

The indigenous component of the Northern Beef Breeding Business project is a joint venture initiative with support from Meat and Livestock Australia (MLA), Indigenous Land and Sea Corporation (ILSC) and Animal Health Australia (AHA) under the Northern Breeding Business (NB2) project framework.

Methods

The project is currently working with twelve indigenous businesses. These businesses manage over 4 million hectares, run around 150,000 head and employ 70 indigenous people.

The project was initiated through personal contact and on property visits with indigenous communities and corporations managing land and operating cattle enterprises. Engagement with elders has been an important aspect of the project from the beginning and has been crucial to ongoing engagement. Most of the indigenous enterprises involved in the project are managed by community owned indigenous corporations. These corporations each have a board of community members which is responsible for strategic decision making. Group membership is diverse and includes board members, station managers, station staff and agricultural advisors.

The NB2 project places emphasis on facilitator training and on building trust within each group. All project facilitators have access to a mentor and the other project facilitators to discuss group progress, to learn from each other and to exchange ideas and experience. The indigenous component of the project utilises facilitation, communication and training processes tailored to suit indigenous property managers, communities and pastoral workers. The process is based around "on country" residential style workshops, peer to peer learning and exchange, specialist input, individual property work and ongoing mentoring. There is a strong focus on member participation, ownership and engagement. The focus is set by group members and the process follows directions established through participatory group input. Four to five workshops are conducted each year. These workshops are based on land operated by group members and involve land and livestock-based activities as well as meeting room sessions. Participants are accommodated together and share meals and informal time, so there is time for stories and yarning, getting to know each other and exchanging ideas and knowledge.

The broader project aims of engaging beef producers with objective data and using this to change business practice are met through engagement with specialist input and communicated through shared group experience. Meetings allow for one on one information exchange as well as group interaction. Group members are at varying levels of management intensification and are engaged with different aspects of land management. There are opportunities for all group members to learn from and benefit through contact with all other group members.

Indigenous group activities are integrated with the broader NB2 project which exposes participants to other aspects of the cattle industry and people from a range of backgrounds. These contacts enable the building of a range of networks across the spectrum of the cattle industry and facilitate a two-way cross fertilisation of ideas, experience and knowledge across groups and across the industry.

Results

Engagement with the process, with other group members and with industry personnel is a highlight of the group activities. Indigenous pastoral workers, land owners and managers have demonstrated a hunger for information and for engagement with the wider cattle industry. Group members have been operating businesses for some time and have been aware of other indigenous cattle enterprises but often have not made contact or worked together and have largely not engaged with the broader industry. These meetings and workshops have provided welcome opportunities for people separated by large distances to meet, yarn and share experiences, knowledge and information.

The project has been operating for four years and members have attended at least four meetings/workshops each year. Awareness of the importance of data, of collecting good data, collating and analysing the data and using the results for development of strategic management interventions has grown. Members are now ready to use data management templates developed by the project throughout their businesses. Opportunities to learn about research and technological developments have been embraced by group members as has the opportunity to meet with and discuss common issues with non-indigenous industry members.

Group meetings and workshops are designed to encourage a cross flow of information, experience and knowledge and this is leading to practice change. A number of strategic and operational management interventions have been implemented by group members. These include improving reproductive efficiency, changing turnoff strategies, infrastructure improvements and an increased focus on supplementation.

An important aspect of the project is the use of mentoring both formal and informal. Group membership is highly diverse in terms of expertise, experience, knowledge and aspirations. The businesses range from large scale beef breeding enterprises to smaller beef businesses, enterprises with a focus on managing for environmental outcomes such as carbon sequestration and savannah burning, cultural tourism and indigenous ranger programmes. The open, participatory nature of meetings means that all members are able to contribute to discussions and there is always something to learn.

Elder members of the group have gravitated towards mentoring roles and this is actively facilitated. In addition to the group workshops and meetings group members conduct property visits, knowledge exchange and management support covering a variety of topics. The group has a natural focus on bringing all members along and the structure of the project enables this.

The broader NB2 project has developed a number of tools to enable and facilitate data collection, analysis and management. Specialists are invited to group meetings and regularly conduct training sessions focussed on data management, reproductive efficiency, pasture and grazing management and business management. The degree of literacy on these topics has improved markedly through the life of the project.

As the project progresses group members aim to broaden the focus to incorporate broader aspects of land management and include multi-functional approaches such as land management for environmental, cultural and social outcomes. This will open opportunities for two-way information flow and co-design and will provide opportunities for employment, training and income diversification.

Discussion

The project has built significant social capital within the group and with industry members engaged with the group. A combination of time spent on country, formal and informal time spent together and a generosity of spirit on behalf of land owners and custodians has enabled the development of group cohesion and trust. To provide an example of co-design, the principles of operation of this group, a group of indigenous cattlemen and women, have been developed by the group. This, in turn, has facilitated an open approach to the application of knowledge, research results and advice and is enabling practice change. The building of trust and group cohesion has been a crucial first step and this takes time, yarning, shared meals, sharing and respect.

Indigenous pastoral workers, land owners and managers have much in common with their non-indigenous counterparts but also have significant differences. Indigenous landowners and business operators have different aims and aspirations to non-indigenous landowners and business operators and operate under a different land tenure/land ownership framework (Barnett 2022).

The beef cattle industry in Australia, like many primary industries is continually facing pressure on costs and the industry, particularly the non-indigenous sector is focussed on using technology to reduce labour and resource use costs. Two of the most important aims of indigenous communities engaged with the cattle industry are employment and training. Improved engagement of indigenous pastoral workers, land owners and managers with the broader industry and participation in industry events and activities may deliver positive outcomes in terms of stable employment and staffing levels and opportunities for indigenous and non-indigenous industry participants. For this to become reality indigenous and non-indigenous industry members must continue to engage in dialogue and create frameworks for meaningful discussion.

Group members are also considering other, innovative aspects of land management which may provide opportunities for employment, training, income diversification and engagement with non-indigenous land managers. These include landscape management for environmental outcomes such as carbon sequestration, biodiversity conservation and regeneration and will come into focus as the group continues to grow. In many cases these enterprises and activities will be more important than the operation of a cattle enterprise on the land. These aspects of land management and enterprise operation will also benefit from two-way discussion, listening and learning and may involve increased engagement with the emerging environmental management sector and potentially provide direction for the broader cattle and land management industries.

Many people involved in land management in Australia, indigenous and non-indigenous have seen a future where indigenous and non-indigenous, scientific and experiential, community driven and corporate ways of managing land are combined to create land management approaches that are multi-functional and appropriate for this landscape and will care for the country and the people into the long term (Massey 2017). There are those also, who say that this possibility provides real cause for optimism for the future of the planet (Tacey 1995). “If we are to make changes of this kind, we need to talk with the whole country about it” (Gammage 2021 p. 183.).

For these dreams to become reality there is a requirement for dialogue, for sharing, listening and the creation of opportunities to move forward together.

This project with the support of MLA, ILSC and AHA has taken steps towards developing a framework for working together for the long-term benefit of indigenous cattlemen and communities and for the broader Australian cattle industry.

Acknowledgements

The authors would like to acknowledge the support and generous welcome of the owners of land on which project activities have been conducted and for the ongoing contribution of all NB2 Indigenous group members.

The support of Meat and Livestock Australia, The Indigenous Land and Sea Corporation and Animal Health Australia is gratefully acknowledged.

The input of specialists including representatives of Bush Agribusiness, Range IQ, Think Digital, Kick Gate Veterinary services, Galf Cattle, MDH, QDPI, Landcare Australia is highly valued.

The Northern Territory Rangeland Management Course: growing the next generation of land managers

Holzapfel, S[1]; Williams, M[1]; Eastaughffe, J[1]; Pettit, C[2]; Kain, A[3]

[1] Northern Territory Department of Agriculture and Fisheries, Katherine; [2] Northern Territory Department of Agriculture and Fisheries, Darwin; [3] Northern Territory Department of Agriculture and Fisheries, Alice Springs

Key words: Extension; Pastoral Industry; Rangeland Education; Cattle Station

Abstract

Productive rangelands are vital to the Northern Territory (NT) pastoral industry but require careful management of grazing pressure to prevent rangeland deterioration. This is generally the responsibility of station managers, who often began their careers as station hands. However, despite it being a large component of a pastoral business, rangeland management is not often included in station hand training.

The NT Rangeland Management Course (RMC) aims to bridge knowledge and awareness gaps in grazing land management within the NT pastoral industry. The RMC is a free, one-day, on-station workshop, designed using hands-on, interactive learning for NT cattle station staff new to the region/industry. It is a series of classroom and paddock presentations and activities, covering topics including pasture composition and dynamics, land condition, carrying capacity, weeds and poisonous plants, cattle nutrition and using fire as a management tool.

In 2021, the RMC was upgraded and expanded. Between 2022 and 2024, the course was attended by 219 staff from 25 cattle stations, representing over seven and a half million hectares of pastoral land. The feedback received from the NT RMC participants during this period indicated increased interest in the topics covered, and suggested the course structure and delivery is effective in providing a practical introduction to rangeland management that is relevant to their station duties. The annual recruitment of new station hands and high turnover of staff in land management service delivery agencies means there will be an ongoing need and demand for the RMC in the future.

Background

Productive rangelands are vital to the Northern Territory (NT) pastoral industry. They provide low input, low-cost pasture allowing cattle producers to run large numbers of cattle (over large areas) where it is not always feasible to grow or buy in other livestock feed due to climate and remoteness. However, Australian rangeland pastures have evolved with very little grazing pressure. This is especially the case in the NT where, prior to infrastructure development, the landscape had limited water available for native grazing animals (e.g. macropods) for much of the year (James *et al.* 1999). The introduction of livestock (predominately beef cattle) has led to higher, more continuous and more selective grazing pressure, which has led to the loss of palatable pasture species, reduced ground cover and contributed to decline in land condition. This directly impacts pastoral businesses by reducing the productive capacity of the landscape.

Matching grazing pressure (i.e. stocking rates) to the safe carrying capacity of the country is a key practice station managers can implement to prevent deterioration of pasture and land condition or help mitigate the effects of historic overgrazing (O'Reagain *et al.* 2014). Doing so requires knowledge of pasture species, pasture yield, land condition monitoring, cattle numbers and feed intake, cattle nutrition, and strategies or tools available to assist in calculating and achieving sustainable stocking rates. However, the career progression into a station management role often begins as a station hand and does not usually involve exposure to or training in grazing land management until the person is in the decision-making role. Ideally, future station managers would start building their understanding of NT rangelands and maintaining long-term productivity well before they are required to make decisions, but it is uncommon for station hands to be aware of, trained or involved in the rangeland management side of pastoral businesses.

The Northern Territory Rangeland Management Course (RMC) is a workshop originally developed and delivered by the Northern Territory Department of Agriculture and Fisheries (NT DAF). Its' purpose is to provide pastoral businesses access to relevant, entry-level rangeland management education for early-career station hands. The RMC provides station staff, who have often come to the property as school-leavers from interstate, with an introduction to the unique environment and production system they work in, an awareness of the impact grazing can have on rangeland pastures (and in turn, cattle production), and an understanding of what grazing management strategies they are unknowingly assisting with in their day-to-day roles on their properties.

While the RMC has been delivered on stations since the early 2000s, this paper assesses RMCs run throughout 2022, 2023 and 2024, looking at the course structure, feedback received, the suitability of the course to the target audience and potentially other industries or regions.

Method

Prior to 2021, the RMC had been a relatively small and home-grown product, funded by the Northern Territory Government for almost 20 years. It was initially designed for stations in the Barkly region (Central-east NT) and then adapted for the Victoria River District (VRD) (North-west NT). In late 2021, the Australian Government, through the Northern Hub, funded the Next Generation Land Managers project which funded all RMC activities from 2022 to 2024, including upgrading the content and delivery of more courses.

The existing course content (PowerPoint presentations, accompanying activities and a printed workbook) was updated throughout 2022, both to incorporate new research findings and create more modern and visually appealing materials for the target audience (station staff, generally 17 – 25 years of age). A new version of the RMC with content relevant to the arid region was created for Central Australian stations, so that three regionalised versions of the course were available: Barkly Region, Big Rivers Region (replacing VRD) and Central Australian RMC. A modernised look was developed and applied across the suite of materials. Branded merchandise was introduced to use as course materials and prizes for participants (pens, notebooks, caps).

The general structure of the RMC was not altered much from the existing course. From 2022 to 2024, the RMC was offered free of charge to stations across the NT though public advertising and existing connections between NT DAF and station managers. It was delivered on-station by NT DAF extension and rangeland research staff who travelled to each station with all materials and equipment required. Stations were requested to have 8 to 20 participants in the course, which could include staff from neighbouring properties, and was not limited to staff in station hand roles. Each course was flexible according to what suited each station and would generally begin after breakfast (e.g. 7am) and finish mid-afternoon. Participants were welcomed with an icebreaker activity upon arrival and provided with resources/materials (workbook, notebook, pen, textbooks/guidebooks, optional resources). Throughout each course, NT DAF staff facilitated a series of PowerPoint presentations, group discussions tailored to the station, and both indoor and outdoor interactive practical activities. Topics covered in the series of modules included: climate variability, pasture dynamics, species identification and pastoral value ("3P" concept), land condition and monitoring (ABCD framework), forage budgets and carrying capacity, cattle nutrition, weeds and poisonous plants, using fire as a management tool, resources and tools available, and how these things can be applied on NT cattle stations.

Prizes were awarded to participants who were the most engaged at each course, and feedback forms were completed by each participant. Where the station manager couldn't participate in the course, the deliverers liaised with them afterward to discuss what their staff had learnt, offer to work with them further, and gauge interest in them hosting another course the following year for new staff.

Results

Between 2022 and 2024, NT DAF delivered 20 Rangeland Management Courses. The 219 participants were from 25 different cattle properties (11% of all pastoral leases), representing 75,837km^2 of grazed land, and 13% of the total pastoral lease area in the NT. This included two Western Australian properties (east Kimberley region). Most participants were early-career station staff (~77%); with some station management staff (~7%), and service providers, agricultural business representatives, and research staff (~16%) also attending.

The average feedback score out of 5 for whether participants would usually have attended a course like this, and their prior knowledge on the topics covered were 3.6 and 2.6 respectively (Fig. 1, orange colour group). For questions on the presentation, delivery, structure and incluson of activities, the average score was between 4.6 – 4.9/5, except for "should there have been more time spent on activities/in the paddock?", which received 3.1/5 (Fig. 1, blue colour group). All questions on whether participants will use learnings from the course in future and increased interest in the topics scored 4 – 4.5/5 (Fig. 1, green coulour group). The average overall value score was 4.6/5 (Fig. 1).

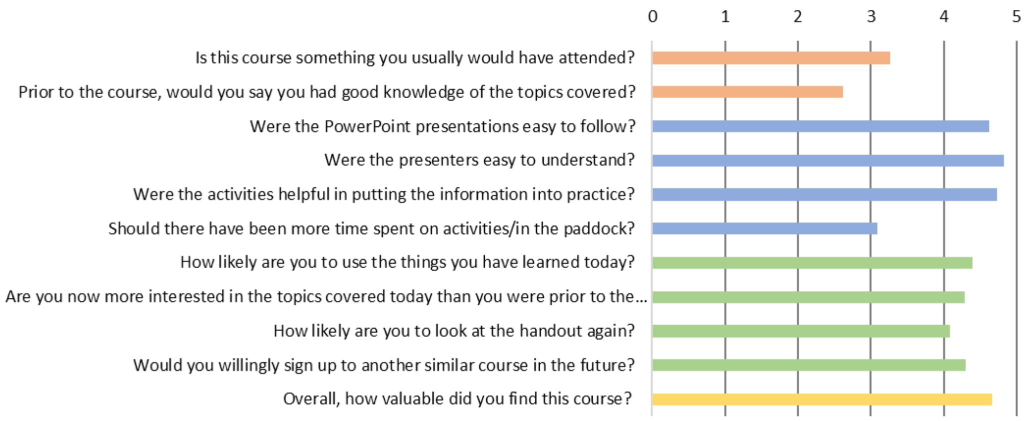

Fig. 1: Feedback from RMC participants from 2022,2023 & 2024, for questions which asked for a 0-5 rating (0 being very unlikely or very low, and 5 being definitely or very high)

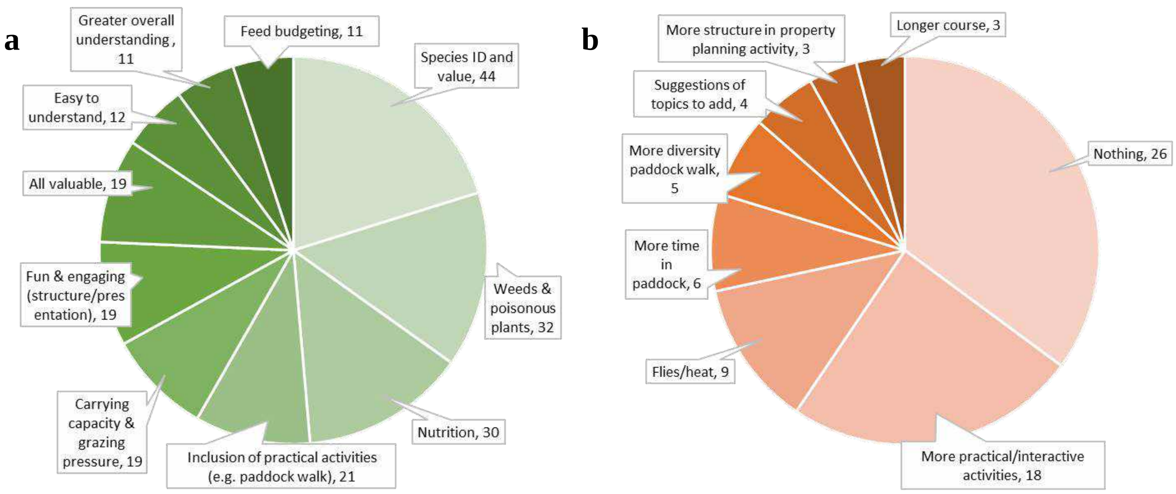

Fig. 2: RMC participant feedback from for the questions a) "Any standout things that were useful, interesting or surprising?" and b) "What wasn't so great, what should we change before we run the next course, or any other comments?". Answers are grouped as themes and ranked by occurrence (out of 219 participants)

When asked for standout/interesting/surprising things from the course, the most common themes in feedback included: species ID and value (44), weeds and poisonous plants (32), nutrition (30) and the inclusion of practical activities (21) (Fig. 2a). The most frequent feedback themes on what could have been done better included: nothing (26) and more practical/interactive activities (18) (Fig. 2b).

Discussion

Many stations offer training for first-year station hands, such as cattle handling, horsemanship schools and other skills required in day-to-day work, but there are few stations with staff inductions that include training on rangelands or pastures. There is other grazing land management training available to station staff for a fee. However, it is at a higher level than first- or second-year station staff need to know. In 2022, 2023 and 2024, 25 cattle stations/properties opted to host or send staff to an RMC, indicating that there are a large number of pastoral properties interested in providing this training for early-career staff. In addition, the RMC was free and could be run on their stations with content tailored to them, which, may have reduced barriers that prevented stations seeking similar training before. Having 25 pastoral properties involved in RMCs also facilitated connections between DAF staff and 25 station managers, which is valuable in that the remoteness of stations can be a barrier to forming industry-government relationships, and for the significant amount of pastoral land in the hands of these 25 managers.

The way the RMC was structured and delivered rated highly in the feedback received. The target audience are often kinesthetic and/or visual learners and not usually the type of people that enjoy textbooks and lectures. It is also not uncommon for literacy and numeracy to be a barrier for some station staff, particularly those that found classroom learning difficult in school. To ensure the RMC catered to this kind of audience, multiple visual, verbal and interactive components were incorporated. These included activities that involved group discussions so that participants could share knowledge/experiences, hands on activities that simulated putting theory into practice (e.g. using property maps to calculate carrying capacity), and a visit to the paddock to relate what they had learnt inside to how it looks on their property. The paddock visits included participants collecting and identifying pasture species, scoring the land condition as a group, discussing soil types and biocrusts, estimating yield, and pasture cuts to estimate yield. High feedback scores for course structure and inclusion of activities, particularly the time spent in the paddock, indicate that this approach was engaging and effective for this audience. Additionally, some feedback suggested the RMC could include even more interactive activities.

Many participants indicated they had limited prior knowledge of rangelands, northern pastures or the northern beef industry, both through written and verbal feedback. Most station staff in the NT have come from a variety of different agricultural and non-agricultural backgrounds, in vastly different areas and climates (pers. obs.).

Hence, the RMC content was designed to be understood by someone with no previous knowledge of the region and no science or agricultural background. Presenters used plain English, or slang terminology where possible to describe technical concepts and processes, rather than using scientific language that participants may not be familiar with. The deliverers were also flexible in the way each topic was presented, spending more time on things that were highly relevant or of interest to participants, and adapting presentation styles to the people in the room based on where they were from or what previous livestock/pasture experience they had. The average rating for how easy presenters were to understand was 4.8/5, so the level of language used to describe scientific processes that can be quite complicated was effective. The rating for if participants were more interested in the topics covered after the course was 4.3/5, and while this is not directly a measure of knowledge increase, it indicated that participants were much more aware of what was covered, and therefore more inclined to seek further information in future.

Delivering the RMC was also a valuable opportunity for new DAF staff to learn about rangeland management, enhance their public speaking and facilitation skills, expand their networks, and engage directly with producers. From 2022 to 2024, six DAF staff delivered their first RMC and worked with producers they had not met before. This, along with the positive feedback received from station managers and course participants has led to support from multiple organisations for the course to continue, and there has been interest to expand the course into other states. The RMC could also be used as a model to provide education to on-ground staff in other rangeland-based industries, offering an introduction to best practice land management and the "why" behind management strategies, and encouraging staff to seek a deeper understanding of the environment they work in. The annual recruitment of new station hands and high turnover of staff in land management service delivery agencies means there will be an ongoing need and demand for the RMC in the future.

Acknowledgements

From 2021 to 2024, the NT RMC was funded by the Australian Government through the Northern Hub project: Next Generation Land Managers. The authors would like to acknowledge all NT DAF employees who have assisted with upgrading and delivering the RMC. The authors would also like to acknowledge the contribution of the creator of the original RMC, Chris Materne.

[2]Department of Primary Industries, Queensland. Rockhampton, Queensland, Australia

Key words: Capacity building; Advancing Beef Leaders; Impact; Influence

Abstract

The Australian northern beef industry faces significant challenges in environmental stewardship, economic sustainability, and human resilience. The next generation of industry leaders must understand, develop, advocate for, and implement solutions to these issues. To support this process, Advancing Beef Leaders (ABL) was launched in 2020, as a joint initiative led by the Queensland Department of Primary Industries (DPI), and supported by private sector collaborators. A capacity building program, ABL aims to develop groups of emerging producer and community leaders who are skilled and enthused to pursue positive change in their industry, regions, and personal businesses. The focus of the program is to overlay relevant beef industry technical content with appropriate personal development, governance, and communication skills; encouraging participants to build stronger peer and mentor networks and spark the confidence needed to influence effectively in their businesses, community, and industry. By mid-2023, from 53 past participants there were 22 appointments to community and industry committees within two years of finishing their ABL programs. Also from the 53 participants were 45 examples of leadership progress such as applying for a higher-level leadership program, progressing careers, and getting directly involved as a co-operator in industry RD&E. Graduates have reported applying ABL learnings to their beef businesses, including adoption of on-property improved practices, better financial literacy, focus on drought resilience and business planning, earlier attention to family succession, and improved communications. Recently, another 22 new participants were selected for the 2024/2025 cohort. Advancing Beef Leaders has proved to be a program that opens pathways to leadership, enhances industry impact and adoption, and develops influence for graduates. With a growing interest from across Australia, the ABL program is excited to begin expansion nationally.

Introduction

Australian family beef businesses face a complex mix of biophysical, productivity, financial and family (people) challenges (Rolfe et. al. 2016). Better business management involves balancing these facets for long term success. Equally, the broader beef industry faces similar challenges at a larger scale beyond the farm gate. As these challenges grow, so does the need for technical and economic training. Agriculturalists the world over, regardless of the size of the enterprise, are motivated by the need for knowledge (Larard, 2022). In response to this, Governments and Natural Resource Management groups are investing significant resources to restore landscape health and productivity. Fundamental community expectations also include the beef industry achieving broader environmental outcomes such as reducing industry greenhouse gas emissions

(Rolfe et. al. 2016). Due to these social licence and economic pressures, it is no longer enough for family beef businesses to only be good at the basics of beef production. Appropriate resource management, savvy cattle marketing decisions, and managing the business's finances are management skills currently required to succeed in a multimillion-dollar beef business. Australia's beef producers need to move from thinking they are 'just' cattleman, to learning the market-centric approaches required of significant commodity suppliers (Larard, 2022).

Currently there are several leadership programs, scholarships and bursaries available to people in Australian agriculture. These include but are not limited to: The Nuffield Scholarship, Australian Rural Leadership Program, Rising Champions and the Zanda McDonald Award. All provide training for participants in increasing practical skills, industry knowledge, management skills and techniques through tailored mentoring programs, where graduates are well documented to progress on to significant industry roles or build family or corporate businesses. The Queensland Department of Primary Industries (DPI) identified an opportunity to develop a leadership program specifically for the northern beef industry, with a focus on family businesses as well as placing ABL as a pathways program for higher-level leadership programs.

In 2020 Advancing Beef Leaders (ABL) was launched with a small pilot group of beef producers and industry professionals in the Charters Towers district of North Queensland. The program aims to develop groups of emerging leaders who are skilled and motivated to pursue positive change in their industry, communities, and personal businesses. The program has now been delivered to seven peer cohort groups and this paper outlines the design of the program and its impact in the Queensland beef industry.

Methods

Participant selection

Participants for each cohort are selected by a rigorous and transparent selection process including a written application and interview with a selection panel. Selection criteria include qualities that indicate focus and passion for the beef industry, willingness to address industry challenges by being involved in community and industry leadership roles, and ability to work within a group. Peer groups are put together with eight beef producers, two agribusiness personnel, and one extension officer.
Each cohort of participants is facilitated and coordinated by an experienced industry professional facilitator and a DPI extension officer.

Program components

The ABL program is delivered over 12-months mostly through online meetings for 2 hours once a week for about 22 weeks of the year. The online sessions deliver content from six training modules: Understanding self and others; Governance; Business planning and financial fundamentals; Industry technical foundations; Industry spheres of influence; and Communication skills. Each module is presented by a mix of experts and other beef producers who practice the skills in their business.

There are three face-to-face meetings throughout the year including an introduction to the first module (Understanding self and others), a two-day supply chain tour and the final two-day communications module and graduation event.

In the second half of the year, participants work in a smaller group on an action learning project. Projects are designed by the group to deliver something that will benefit their community or the broader beef industry. The learning objectives of the group project include: understanding the importance of good group governance and function, application of program learnings from all modules, and learning how to collaborate with all relevant stakeholders and contribute appropriately to a community or industry topic of interest.

Participants are paired with a mentor of their choosing that they believe will help them address their goals and skill development targets. Mentor and mentee pairs meet regularly throughout the year in a private capacity.

Alumni

Graduates of ABL join the alumni network that fosters continuous improvement and peer learning through scheduled activities, training opportunities and other program events. Alumni are encouraged to take opportunities to become ABL mentors, guest speakers or hosts of activities for face-to-face events. In 2024 The Connection Table was launched for alumni as a “What next” platform providing leadership pathways to amplify their impact beyond completing the program.

Governance

ABL continues to be developed and delivered under a collaborative private and public sector partnership model. Each regional cohort is delivered by a private sector lead facilitator and a DAF coordinator. Each participating staff member receives substantial skills development, as well as significantly enhancing their industry networks. DPI co-ordinators are also able substitutes for the lead facilitators and program manager when required, giving them the opportunity to hone valuable facilitation and project management skills fostering professional development. There are also opportunities for all alumni to further their skills by going on to be mentors of future participants of the program, as well as be involved in program committees, planning and delivery. This structure of re-engaging alumni to lead within the program ensures the foundational values and culture remain as the program continues to expand.

Results

Since 2020, 53 participants have graduated from 7 cohorts. 22 graduates (41.5%) have been appointed to community and industry committees within two years of finishing their ABL programs. There are 45 examples of leadership progress such as applying for a higher-level leadership program, career progression, and becoming directly involved as a co-operator in industry RD&E. Graduates have reported applying ABL learnings to their beef businesses, including adopting improved practices on-property such as better financial literacy, focusing on drought resilience and business planning, earlier attention to family succession, and improved communication. The current 53 alumni remain connected to the program through social media platforms, attending a biannual forum and most recently, through partnering with The Connection Table.

During the 2024/2025 mid-point reflection step, the current 22 participants have already recognised improved confidence in their approach to new opportunities for personal and professional growth as well as gratitude for a new level of awareness and understanding of the beef industry supply chain.

Monitoring & evaluation (M&E) of past ABL cohorts recorded a consistently excellent participant satisfaction rating >85% for all online learning modules, and >90% rating for in-person events. The mid-point reflections of the first three modules of the 2024-2025 program has similarly documented exceptional results. Participants answer four questions using a rating between 1 and 7. The averages of the results of these questions are expressed as percentages in *Table 1*. ABL modules are designed as ‘tasters’, including skills and knowledge important to leadership and beef industry professional development. This program, Modules 1-3 have shown significant before-after knowledge improvement, are averaging >90% score for the value of the information to the individual’s business, and average >85% for the likelihood of making change/s.

Table 2. ABL participant feedback scores, modules 1-3 (2024/2025).

	How would you rate your knowledge and understanding BEFORE this module?	How would you rate your knowledge and understanding AFTER this module?	How valuable was the information you have been provided in the module in assisting you to conduct your business?	How likely are you to make this change/changes?
Module 1 Understanding Self and Others	47%	80%	97%	92%
Module 2 Governance	40%	77%	88%	84%
Module 3 Financial fundamentals	53%	79%	89%	82%
Average	**47%**	**79%**	**91%**	**86%**

Discussion

ABL has been developed as a tailored leadership program that overlays relevant technical skills with self-development that fosters attitudinal change and enables participants to build stronger networks and develop the confidence to contribute and influence. This is demonstrated through the large number of participants who have moved from the program into community and industry roles. The program builds capacity to create awareness of the significant challenges the beef industry faces throughout the supply chain that are specific to environmental stewardship, economic sustainability, and human resilience and participants reporting leadership progress are better placed to help address these challenges.There have been numerous occasions where participants have acknowledged that the skills and confidence developed through ABL have allowed for improved communication and conversations on property, which has resulted in better relationships and positive impacts on succession within family businesses.

Nettle et al (2022) reports that extension strategies that most facilitate practice change are peer-to-peer groups and one-on-one advice and they are most impactful when stacked together. This is consistent with the results ABL has achieved in participants adopting new practices that include better financial literacy, focusing on drought resilience and business planning, earlier attention to family succession, and improved communication. ABL participants were selected based on application criteria that also considered their likelihood to contribute to group culture such that learning from other group members was possible. Group engagement through face-to-face events was critical in building relationships necessary for successful online engagement. Creating groups with a balance of beef producers, industry professionals and service providers meant a range of personalities, technical skills and industry experience needed to be navigated with skills learned in the program. One-on-one advice was provided by mentors with whom participants met with on a regular basis.

The ABL Alumni recognise the program as being pivotal in their personal and professional development, often referring to the program as "life changing". The alumni have developed a sense of ownership of the program with a culture of support for each other, further increasing the cohesiveness of Alumni peer to peer learning and relationships. They have continued to expand their networks and the recent launch of The Connection Table has enabled further pathways to leadership development (The Connection Table, 2023). ABL fits comfortably into the landscape of agricultural leadership programs as a first steps program. ABL provides a pathway to more advanced or specific programs such as The Nuffield Scholarship, Australian Rural Leadership Program, Rising Champions and the Zanda McDonald Award.

ABL has positioned itself as a critical change agent, increasing the capacity of individuals for meaningful contribution and addressing challenges across all beef industry sectors. The successful delivery model of topical modules, mentoring partnerships, and group action learning projects facilitated by trained extension and adult learning practitioners, has proven ABL to be a leadership development program unique amongst the beef industry.

The ABL program has built a respected reputation within the beef industry due also to the high calibre of ABL alumni . As a result, the ABL program is now in demand across other states and territories of Australia. There is much to gain for the beef industry in Australia through slowly expanding the footprint of the ABL program beyond Queensland. Improving the knowledge and capacity of the next generation of beef leaders will only benefit the beef industry further.

As of 2025/2026, ABL will endeavour to meet interstate demand for the program and begin to expand across the Northern Australia and New South Wales.

Acknowledgements
The ABL program gratefully acknowledge the funding provided by Australian Government's Future Drought Fund and the Queensland Government's Drought and Climate Adaptation and Reef Water Quality Programs. Thank you to Alison Larard for the passion and commitment to the program development as well as to supportive DPI colleagues Joe Rolfe (deceased), Bernie English, Tim Emery, Kylie Hopkins and Emma Knight who have contributed to the growth of the program. Thank you to the key facilitators Ben Reeve and Amanda Roughan for their group facilitation to date. Thank you to the various professionals who deliver the program milestones, and to the industry leaders who have volunteered their time as mentors. Most importantly thank you to the ever-growing Advancing Beef Leaders Alumni who continue to have positive influence by showcasing impactful leadership across all industry tiers.

Grazing Fundamentals EDGE: partnerships, collaboration and co-design in practice

Plumbe, M[1]; Bawden, H[1]; Tschirner, A[2].

[1] Meat & Livestock Australia, Armidale, Building W41a, The Short Run, UNE, NSW, 2351, Australia, mplumbe@mla.com.au; [2] South Australian Arid Lands Landscapes Board, PO Box 297, Port Augusta, SA, 5700, Australia

Key words: Grazing management; land management; peer-to-peer learning.

Abstract

Across the Australian southern rangelands, 54% of the total land area is utilised for extensive livestock production (Hacker and McDonald 2021). With such a significant influence over land management, it is critical that pastoralists are supported to implement land and livestock management practices that ensure ongoing sustainability of both landscapes and businesses. The Grazing Fundamentals (Southern Rangelands) EDGE course is a capacity building workshop that builds foundational knowledge and skills in the areas of land management, grazing management and livestock production. It has been developed to suit a range of learning styles with the inclusion of presented information, classroom-based activities and hands-on exercises. Using varied teaching and group facilitation methods, the workshop encourages attendees to share their knowledge and observations, supporting peer-to-peer learning.

The initial delivery of this workshop in South Australia was highly successful, engaging 146 workshop participants who manage a total of 22 million ha and reported an overall satisfaction score for the workshop of 9.4/10. 92% of participants indicated an intention to change management practices as a result of attending the workshop, with the most common area of change being to begin assessing land condition. The collaborative nature of the project is a key factor that determined the workshops success. In instigating the project, partnerships were formed with relevant industry stakeholders to effectively leverage the varying resources and skillsets of partner organisations. This allowed consensus to be formed on technical concepts to standardise terminology and messaging between northern and southern rangeland systems. Content was co-designed and delivered by project partners, ensuring relevance and appeal to the target audience.

Introduction

The Australian southern rangelands are described by Hacker et al (2019a) as lying outside of adjacent mixed farming zones with annual rainfall mostly within the 250mm isohyet and rainfall patterns being either winter dominant or aseasonal. While definitions of the southern rangelands vary (Foran et al. 2019), this definition was deemed most relevant as it aligns with the production area this extension product targets.

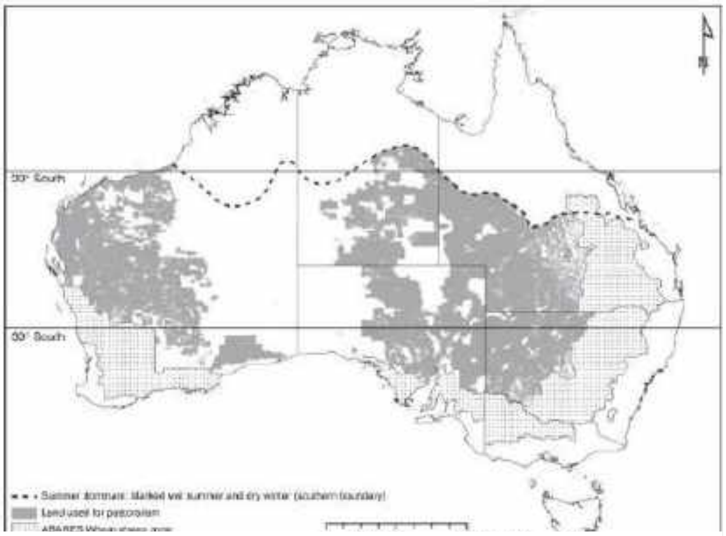

Figure 1. Approximate boundaries of the southern rangelands
(Hacker et al. 2019a).

As is shown in Figure 1, the southern rangelands makes up a significant portion of the Australian land mass. Within the southern rangelands 54% of the total land area is utilised for extensive livestock production (Hacker and McDonald 2021). With such a significant influence over land management, it is critical that pastoralists are supported to implement land and livestock management practices that ensure ongoing sustainability of both landscapes and businesses.

Decades of primarily public investment in research and development has led to a valuable knowledge base being available for best practice grazing management, land management, and livestock production principles within the Australian rangelands context. However, collation of this literature into producer facing resources such as technical guides and capacity building workshops has largely been limited to northern rangelands systems and the southern rangelands of New South Wales. These existing products include Grazing Fundamentals (Northern) EDGE, Grazing Land Management EDGE and Tactical Grazing Management. The southern rangelands are unique to Australia's northern rangelands as they incorporate a variety of chenopod dominated land systems, have a diversity of both C3 and C4 plant species and are utilised for grazing of sheep, cattle and goats. For this reason, it is important that resources be designed specifically for the region.

This extension resource gap had been identified by various southern rangeland practitioners. Through the Australian Governments Future Drought Fund, the South Australia Arid Lands Landscape Board (SAAL) delivered the 'From the Ground Up' project, a multi-year demonstration type project designed to build drought resilience. Within this project, SAAL partnered with Meat & Livestock Australia (MLA) to develop and deliver a one-day training course that covered the foundations of animal nutrition, land management and grazing management, specifically for the southern rangelands.

This course is known as Grazing Fundamentals (southern rangelands) EDGE. Course objectives are to build actionable technical knowledge and skills with pastoralists to increase the environmental and economic sustainability of pastoral businesses.

Methods

In delivering this project, MLA engaged six technical experts to contribute under the structure of a project Working Group. This group was involved in developing the course outline, content and extension design, delivering the course and providing strategic and tactical advice on project delivery. This level of collaboration bought together a diverse range of skills, knowledge and experience across research, development and adoption within the Australian pastoral industry.

The course was designed to cover three core modules of nutritional requirements for animal production, grazing land ecosystems and grazing management. A focus was also placed on teaching methods to ensure it incorporated practical activities, supported peer-to-peer learning and appealed to varying learning styles.

Course development

The approach of the project team was to use existing industry resources as a foundation for the course to reduce the need for starting a literature review from scratch. Content updates and/or gaps were identified, and literature was subsequently identified, collated and reviewed to inform the development of new material. Sections that required specific content development for the southern rangelands were climate, the management of shrublands and grazing management. Initially, a participant/deliverer technical manual was completed, which then guided the development of workshop slides and activities.

A significant aspect of the course development process was the delivery of a pilot workshop to SAAL staff and stakeholders with a knowledge of the region and target audience. Feedback from this group, combined with reflections from the working group strongly informed the final product. A key outcome from this was better defining the target audience and intended learning outcomes. The audience was defined as younger industry participants or those with less experience and exposure to scientific rangeland management concepts. The learning outcomes were sharpened to focus on key principles of rangeland management and how they may be implemented on-ground.

Course content was developed to suit diverse learning styles, using a mix of presented information, classroom-based activities and hands-on exercises. A focus was placed on deliverers utilising a range of presentation and facilitation methods to encourage participants to share their experiences, ask questions and learn from each other, through a supported peer-to-peer learning process.

Course delivery

Course delivery occurred as two distinct series in August and October 2023. These times and locations were guided by SAAL staff with local knowledge of participant availability and competing events.

Courses were co-delivered by two working group members, with a third working group member also co-delivering three courses under a trainee model. Alternating delivery of the workshop sections between deliverers allowed all to become comfortable with all course material, facilitating future commercial delivery.

Course review

Courses were reviewed primarily by a formal participant evaluation form. Course deliverers, SAAL representatives and Working Group members present at each workshop also provided feedback. To review and update the course in response to evaluation forms and peer observations, two different processes were followed.

In the first instance, debriefs were held following each workshop to share feedback and review evaluation forms. Wherever possible, changes and updates were made at this time to present the best product for the next workshop.

Where identified updates required more significant changes or research, these were addressed at the end of each workshop series. The primary changes made to the course were the way in which practical activities and the case study property were presented.

Results

Eleven workshops were delivered to 146 participants, at an average of over 13 people per workshop. These participants represented 66 pastoral businesses and a total management influence of over 22 million hectares, 150,000 head of cattle and 370,000 head of sheep.

The overall value and satisfaction scores for the workshops were 9.1/10 and 9.4/10 respectively. Value scores broken down by module (Nutrition, Grazing ecosystems, Gazing management) show a ratings difference of only 0.1/10 between each module.

Overall intention to implement change as a result of attending the workshop was measured at 92% of participants. Further insight to this figure is provided in Table 1, where the most common intended change to implement, at 64% of participants, was to assess land condition of paddocks.

Table 1. Summary of intended practice change

Will you make any changes?	**Yes %**	**No %**	**Maybe %**	**Already doing it %**	**Not applicable %**
Review livestock nutritional requirements	51	0	19	22	8
Review stock numbers and feed supply around key decision dates	48	0	6	37	8
Assess the land condition of your paddocks	64	0	4	28	5
Work out safe utilisation levels and/or carrying capacity	54	0	16	23	7
Do a forage budget	43	5	38	6	9

Discussion

When considering workshop results, they can be compared to the benchmarks maintained by MLA for delivery of similar industry training programs. A key performance indicator (KPI) for producer adoption programs is to maintain satisfaction and value scores >7.5/10, indicating that this course far exceeded that benchmark with the above listed value and satisfaction scores of 9.1 and 9.4/10 respectively. The consistency of module value ratings is also quite significant in demonstrating the relevance of all three course modules and the consistent high quality of delivery.

Some key learnings gained though the delivery of this project include:

- The target audience and intended learning outcomes must be clearly established at the start of the course design process.
- Having deliverers involved in course development ensures consistency between workshop design and delivery, streamlining progress from one stage to the next.
- Partnering and collaborating with local service providers is highly beneficial in accessing local networks to ensure strong attendance, provision of locally relevant resources and ground truthing of course material prior to delivery.
- Consider course content order to deliver the 'hook' upfront in the workshop. In this instance, the livestock nutrition session was of high interest to producers so was delivered first. This contributed to early and sustained engagement throughout the day.
- The structure of the workshop reinforced the value of activities for engagement, including outdoor, hands-on, 'on your feet' type exercises.

The course supported participants to identify opportunities to enhance their business productivity, resilience and sustainability in relation to livestock and land management. By providing information alongside practical activities, participants were encouraged to consider how they could apply management concepts to their own business. Combined with the expertise of regional service providers, workshop deliverers and peers, participants were also given an opportunity to discuss, share and learn from the experience of other livestock producers and land managers.

The objective of creating an actionable capacity building product specific to the southern rangelands was achieved. Its success is validated in evaluation data that indicates a very high portion of participants intend to implement a change in management practice as a result of course attendance. This course now provides a valuable resource, accessible to producers right across the Australian southern rangelands through a commercial delivery model.

Initiated through an industry partnership and executed through broad collaboration, this project has demonstrated the value of co-design practices to develop and deliver high impact extension and adoption products.

Acknowledgements
The development and delivery of this workshop was led by Meat & Livestock Australia. It was funded by the Australian Governments Future Drought Fund, through the SA Arid Lands Landscape Boards ‘From the Ground Up’ project. MLA and SAAL would like to acknowledge working group members for their significant contributions to this project. This includes Ron Hacker, Dionne Walsh, Deb Scammell, Trudie Atkinson, Tanisha Shields and Jodie Reseigh.

Transformation of tacit knowledge into recommendations for ranchers through rural extension in Uruguay.

Pereira Machín, M[1]; Areosa, P[1]; Carriquiry, E[1]; De Hegedus, P[1]; Leivas, R[2]; De Brum, F[2]

[1] Instituto Plan Agropecuario, Br Artigas 3802, Montevideo, CP 11.700, Uruguay; [2]Instituto Nacional de Investigaciones Agropecuarias, Ruta 5, Brig. Gral. Fructuoso Rivera km 386, Tacuarembó, Uruguay.

Key words: living laboratory; open innovation; extension; grassland management.

Abstract

Grasslands cover more than half of the Uruguayan territory. The Instituto Plan Agropecuario (IPA), a national extension agency, is implementing a project to systematize and promote good grassland management practices (2021-2025). The project considers the knowledge that ranchers have (tacit knowledge) and thanks to which they have been able to successfully develop in a changing and unpredictable environment. This initiative uses an open innovation framework through 26 "living laboratories" installed in different parts of the country. Through a monitoring and evaluation system, 28 key grassland management practices have been identified, which are classified into five macro-variables, which interact with each other and with the broader context. The macro variables are: infrastructure, strategic productive areas (EPA), grazing management, livestock management, and monitoring system. The rancher is responsible for decision-making. Due to limited cognitive abilities, incomplete information, and the complexity of the context, ranchers often adopt a "satisficing" approach rather than "maximizing" when making decisions. To conclude, a conceptual model was developed that describes the main macro variables related to good grassland management practices. Monitoring these macro-variables would allow ranchers to establish their current situation and co-design a route of action together with ranchers and extension technicians. Paddocking is highlighted in the case of infrastructure, the proportion of improved area in the strategic production areas (EPAs), the proportion of the ranch over 5 cm (PRO5) in the case of grazing management, strategic supplementation for livestock management and the importance of having a monitoring system. The work balance reveals that there are agents who have two hours a day to "think" about the management of macro-variables and there are others who, due to the dedication required by routine work, do not have this possibility. Extension has an important role in promoting learning, through integrating and sharing different types of knowledge, and reflective processes and group strategies.

Introduction

Grasslands currently occupy 55 percent of the national territory (MapBiomas Uruguay, 2024), constituting the main feed source for livestock in Uruguay. There is scientific evidence of the importance of grasslands management in determining good economic, productive and environmental results (Torres et al. 2024).

Recognizing that ranchers have an important capital in accumulated tacit knowledge, which is valuable, little known and little understood, the Instituto Plan Agropecuario is implementing a project called “Grassland Management”, which aims to rescue this knowledge, systematize it and make it explicit to the rest of the national livestock industry.

Methods

Twenty-six ranches (cattle and sheep) located throughout the country were selected. The sampling was done by convenience, choosing ranchers who managed grasslands in a way that allowed them to obtain outstanding results.

Under a theoretical framework of open innovation and adaptive management (Holling 1978), each ranch was taken as a “living laboratory” (Higgins et al., 2011) and monitoring was initiated that covered productive, economic, environmental and social aspects (fiscal years 2021/22, 2022/23, 2023/24).

The variables monitored and their frequency were: sward height of each paddock (seasonally), weight of cattle (seasonally), weight of sheep (seasonally estimated); from this information an index was used to estimates a forage balance, Food Plate Index (Duarte et al. 2021). Net primary production area (NAPP) was also estimated. All this information was recorded in a platform called iPasto (Lombardo et al 2021).

Information was collected to estimate meat production, economic results and environmental performance indicators. A typology of ranchers was made, through semi-structured questionnaire, since it combines open-ended questions with a general consultation scheme, allowing flexibility to go deeper according to the answers given by the interviewee to characterize the manager's vision of the aspects that affect grassland management, and the work balance was calculated (Dieguez et al., 2009). The environmental livestock tool (EMAG) (Becoña, 2020), the index of ecosystem integrity (IEI) (Blumetto, 2021) and environmental performance indicators included in the livestock environmental footprint (Paruelo et al., 2023) were applied.

This information was managed in 150 dialogue workshops - biannual frequency - with ranchers neighbouring each laboratory. They were evaluated with a focus on learning.

The database was analysed through descriptive statistics, performing linear regressions and multivariate analysis, using the statistical package Infostat/L version 2017.

Results

The farms analysed were dedicated to cattle ranching, with an average area of 1,295 hectares, ranging from 60 to 5,500 hectares. Regarding production systems, 40% of the farms focused on breeding, 24% operated a complete cycle, while the rest were divided among incomplete cycle (12%), backgrounding (12%), and finishing (12%). The average improved pasture area was 23%, with some farms heavily relying on improvements; 11 of them had over 90% grasslands, and three operated entirely on improved pastures.

Grazing methods varied across the farms. While 24% implemented rotational grazing, 28% combined continuous grazing with rest periods and rotational modules. Another 19% practiced continuous grazing with paddock rest, whereas 7% maintained continuous grazing without rest. Sheep were present in more than half of the farms (52%), with an average sheep-to-cattle ratio (S/C) of 1.21. Meat production levels averaged 114 kg/ha, fluctuating between 70 and 248 kg/ha, while capital income (CI) stood at 92 USD/ha, with values ranging from 28 to 171 USD/ha. The economic input/output ratio was 0.6, with a variability between 0.4 and 0.8.

Net aboveground primary production (NAPP) for the 2021/22 season aligned with the historical average recorded between 2000 and 2024. However, in 2022/23, NAPP was 9% lower, whereas in 2023/24, it exceeded the average by 18%.

A survey conducted during the study identified 28 good practices related to grassland management. These were grouped into five key macro-variables: infrastructure, strategic productive areas (SPAs), grazing management, livestock management, and monitoring systems. Infrastructure included watering points, paddock subdivisions, shade, roads, handling facilities, and the strategic use of attractions based on vegetation heterogeneity. Strategic productive areas (SPAs) incorporated modules designed for high forage production

(MHFP) (Pereira Machín, 2017) and those for preventing forage crises (MFCP) (Pereira Machín et al., 2018), which functioned as deferred forage reserves. Grazing management extended beyond specific methods and instead considered morphogenic factors essential for maintaining plant function under grazing pressure. Livestock management encompassed breeding strategies, ewe management, genetics suited to field conditions, and the strategic use of supplementation to enhance grassland efficiency. Lastly, monitoring systems served as tools to track activities closely, allowing for informed decision-making and proactive adaptation.

At the core of this conceptual model is the decision-making agent, which could be a rancher, a company board, a rural manager, or a family unit overseeing the system.

Data from the monitoring process highlighted important aspects of grassland management. The balance of work showed that while some managers dedicated at least two hours per day to analysing macro-variable management, others were entirely absorbed in routine tasks, limiting their ability to plan strategically. The variation in paddocking and infrastructure played a significant role in explaining fluctuations in meat production. Differences in the improved pasture area were closely linked to the stocking rate, the proportion of the ranch with pastures exceeding 5 cm (PRO5), and overall meat production levels. The proportion of the ranch with pastures above 5 cm was also strongly correlated with stocking rate and meat production.

Strategic supplementation was implemented only in specific cases, and its impact on economic performance was evident only in years of good pasture availability. The proportion of native grassland contributed positively to environmental performance indicators. However, although increasing improved pasture areas resulted in higher sward heights, excessive reliance on pasture improvement came with trade-offs, as it led to higher greenhouse gas emissions due to increased input usage.

Discussion

Grassland management can neither be seen in isolation nor fixed. It is necessary to have a systemic view that considers its changes in the temporal dimension. For the discussion of the results, we will use an analogy with the evolutionary approach developed by Charles Darwin (1859). The interesting thing about Darwin was that he managed to explain the phenomenon of why evolution occurs (Vorzimmer, 1969).

The theory of evolution is based on three pillars: variability, natural selection and heredity (Mayr, 2002). For evolution to operate, there must be variation. In the case of grassland management, if we weight each macro variable as the producer in each of them can be bad, good or excellent; there are 243 possible combinations, where some give very good results, and the worst determine that the companies are out of the game.

In the case of grassland management, the selection is given by the context, and the companies that “learn” survive. Such learning positions them better for future events, because it is based on a better understanding of their ranch and contextual factors. We call this “sustainable adoption”.

In the case of the “selected” ones, for them to endure, there must be a mechanism that transmits these characteristics (*i.e*., the self-replication of DNA in the theory of evolution), here through what we call “cultural transmission” (Cavalli-Sforza et al 1981), which can occur vertically from parents to children or horizontally among ranchers.

Extension must devote efforts to achieve learning and encourage cultural transmission, to “prevent” natural selection from operating wildly.

The producer manages the different macro-variables through a “filter” that is constituted among other things by his purposes, his age, education, production system, and the external context. It is necessary to dedicate time to “think” this management and for that the organization of the work and its planning is important. Decisions are always made with insufficient information, which is why it is said that it is a process with limited rationality, where the result is satisfaction (Simon, 1957). Optimization implies considering the 5 macro variables and it is more realistic to think that the agent prioritizes one or some of them.

One of the key benefits of the conceptual model is its ability to provide guidance through monitoring, helping to assess the current situation and determine the most appropriate decisions for each macro-variable. This process enables self-referencing, which, when combined with a forward-looking vision, establishes a clear course of action.

In this context, infrastructure plays a crucial role, as highlighted by ranchers. Its proper implementation facilitates improved forage management by optimizing grazing distribution and access to key resources. Strategic productive areas are reflected in the extent of improved pastures and their influence on grass height, meat production, and the proportion of the ranch with pastures above five centimetres. These areas also support high concentrations of cattle while maintaining good performance, which indirectly contributes to the regeneration and relief of natural grasslands.

Regarding grazing management, the PRO5 variable emerges as a critical determinant of meat production. Its reference values exceed those traditionally used, suggesting a shift towards more effective and productive management strategies.

Livestock management, which involves both cattle and sheep, along with adapted genetics and strategic supplementation, plays a crucial role as it interacts with all other aspects of the system.

Having a monitoring system is essential for making proactive decisions, allowing for adaptation and course correction when necessary. Without a monitoring system, self-referencing becomes impossible.

Conclusions

A conceptual model was elaborated that describes in a systemic way the main macro variables that make up good grassland management practices. It can be used as a tool for self-evaluation in its different macro variables so that, through monitoring, decisions can be made in advance to improve management. Paddocking is highlighted in the case of infrastructure, the proportion of improved area in the EPAs, PRO5 in the case of grazing management, strategic supplementation for livestock management and the importance of having a monitoring system.

In the case of the improved area, these must be implemented efficiently, taking care of the use of inputs. The role of the grassland as a determinant of good environmental performance indicators is evident, providing the systems with resilience and resistance.

The persistence of the ranches in the long term is based on adapting to the changes of the context (learning in ascending scale), within the framework of the designed route of action. To this end, it is necessary to promote: i) reflective processes (critical thinking) that necessarily require time and ii) group strategies that promote cooperation. The organization of work in a simple way and delegation collaborate, to the extent that it generates time for reflection.

Extension has an important role in fostering learning, through integrating and sharing different types of knowledge, and reflective processes and group strategies.

Acknowledgements

To ranchers, IPA and INIA who made this project possible, our sincere thanks go to them.

Carbon in the rangelands: Developing a training package for pastoralists

Bawden, HT[1]; Connors, H[2]

[1] Dentsu Creative; [2] Meat & Livestock Australia

Key words: carbon; emissions; agriculture; extension; training

Abstract

Agriculture accounts for approximately 17.4% of Australia's national greenhouse gas emissions, of which around 68% is attributable to enteric fermentation (DCCEEW 2022). In line with national and global climate commitments, the pastoral industry will play a significant role in helping to reduce emissions, whilst also acting as a major sink for carbon storage in vegetation and soils.

The ability for pastoralists to be able to calculate, demonstrate and manage their enterprise based on their carbon footprint is becoming important to maintain social license and market access. Enterprises with a low carbon position may also be presented with opportunities around value-adding and business diversification.

When it comes to on-farm emissions reductions or carbon sequestration, Australian pastoralists express concern and confusion, and are unsure what actions to take or who to trust for independent information, thereby stalling adoption. Carbon EDGE, a new training program for the red meat industry, was born out of the need to scale up industry capacity, responding to these adoption challenges.

The process involved the co-design of a two-day workshop with supporting resources by a Working Group of livestock producers, service providers, supply chain representatives and researchers.

Six pilot workshops and two train-the-trainer sessions were delivered in different regions to seek feedback from over 100 industry participants representing 2.9 million ha under management. This included a specific focus on ensuring the program was relevant for rangeland environments.

Covering key terminology and concepts; supply chain and policy drivers; environmental markets; carbon accounting and on-farm interventions, the program aims to provide participants with information to make confident decisions and form an action plan aligned to their own production system and business goals. The success of the program was reflected in satisfaction scores averaging 8.5/10. The need for continued extension in this space was reflected in the project outcomes, with participant confidence levels sitting between 3-3.5 out of 5, and over 90% of attendees indicating their intent to take action following the workshop.

Introduction

Whilst many livestock producers and industry service providers recognise the need to demonstrate action on decarbonisation, there are several barriers to on-farm emissions reductions, sequestration and reporting (Henry unpublished; Farners for Climate Action 2023):

1. An absence of policies or incentives for sustainable practices, whether those be government, supply chain or market-driven.
2. High upfront costs and limited access to capital for investing in sustainable practices.
3. Uncertainties in the methods for measuring and validating on-farm change.
4. Confusion due to mixed messaging and difficulty sourcing information from independent (non-commercial) sources.
5. A lack of independent advisors with the expertise to support on-farm reporting, planning and implementation of emissions-reduction strategies.
6. The pace of research and development for technologies to support on-farm emissions reductions.

Carbon EDGE, a new training program for the red meat industry, was born out of the need to scale up industry capacity, targeting several of these adoption challenges (in particular, points 4 and 5, above).

Consistent with the Adoption Strategy of Meat & Livestock Australia (MLA), Carbon EDGE was designed to increase knowledge and skills of participants, building on other awareness-raising activities already on offer across the sector (MLA 2024). Developed in the context of whole-farm business planning, Carbon EDGE was also designed with a focus on increasing participants' business sustainability, profitability and/or productivity.

Method

This project was undertaken with a team made up of MLA staff, expert service providers and a Working Group. The ways of working were established early in the project, with the implementation of project management protocols and regular project meetings. The project was divided into two stages, with service providers selected to deliver each stage:

1. Stage 1 involved the development of a technical manual. This underpinned the development of other resources in Stage 2.
2. Stage 2 involved the design of the training package using best-practice extension principles. This included the development of training resources, delivery of two train-the-trainer sessions and six pilot workshops, and the project evaluation.

The Working Group, comprising of livestock producers, advisors and technical experts, was used as a sounding board for both stages. The group was formed through an Expression of Interest process, with participants representing different regions and production systems, including the southern and northern rangelands.

Stage 1

The Working Group determined the outline for a "master" technical manual, which could be used with supplementary material to ensure relevance for different regions and production systems. The service provider subsequently undertook a review of Australian and international literature for the development of five modules: Greenhouse gases 101; Greenhouse gas accounting; Carbon credits and carbon neutrality; On-farm emissions; and On-farm sequestration. MLA staff provided additional content for the manual with a focus on livestock production. It was reviewed by the project management team and Working Group before being finalised.

Stage 2

The design of the training package was based on a set of learning outcomes determined by the Working Group:

- Improving carbon literacy and understanding of carbon farming, carbon sequestration and greenhouse gas emissions.
- Increasing participants' level of confidence around the carbon accounts for their business.
- Participants have identified short and long-term actions to reduce their emissions and increase the sequestration occurring within their farming business.
- Participants have the tools and knowledge to critically assess actions which fit within their business.

Information was presented through a mix of visual, auditory, reading, written reflection and activity-based learning. Activities were designed to incorporate a mix of individual reflection, small group work, teamwork, presentation and role play.

An important outcome of the Carbon EDGE program was for each participant to develop an Action Plan to align to their own business objectives and opportunities. The Action Plan was broken down into step-by-step activities to complete throughout the workshop, set out in a participant workbook.

During this stage, the workshop resources were also developed. This included a participant manual (a simplified and more visually engaging version of the technical manual), a slide deck, run sheet, evaluation forms, activity information, and supplementary regional materials for deliverers (e.g. datasheets, case studies).

Based on the content developed in Stage 1 and the learning outcomes identified in Stage 2, it was determined that the program should be delivered in person over two days. The training program was designed using a "flipped learning" model in which participants are provided with information prior to attending and are given the opportunity to revisit the material during the workshop. The flipped learning model for Carbon EDGE was designed to leverage existing online training programs, tools and 'how to' videos.

Pilot workshops were run over a five-month period in different regions of Australia. The pilot workshop deliverers were service providers already involved in the project via the Working Group, who undertook online train-the-trainer sessions before the workshops. Extensive preparation was required for deliverers to familiarise themselves with the material and customise the information for each region (environment, production system, livestock enterprise, markets etc). Two deliverers, and MLA staff, were present at each pilot workshop.

Updating the training program was an iterative process, with adjustments tested after each of the pilot workshops. A major revision of the training package was completed following collation of the workshop feedback from all six pilots, taking into account the reflections of workshop deliverers. An additional train-the-trainer workshop was offered in person for new deliverers after this process had been completed.

Results

Six pilot workshops and two train-the-trainer sessions were run in different regions to seek feedback from over 100 industry participants representing 2.9 million ha under management (see Table 1). Participants travelled extensive distances to workshops, with representatives from rangeland production systems present at four of the six sessions – Mackay, Roma, Narrabri and Alice Springs.

Table 1. Pilot Carbon EDGE workshops delivered

Pilot location	Date	Producers	Others
Mackay, QLD	9 – 10th November 2023	10	0
Benalla, VIC	5-6 December 2023	15	5
Roma, QLD	15-16 February 2024	20	1
Narrabri, NSW	20-21 February 2024	16	2
Coonawarra, SA	27-28 February 2024	15	4
Alice Springs, NT	18-19 March 2024	9	10
Totals		85	22

Participant feedback

Pilot workshop participants completed feedback and evaluation forms to support the review of the program. The forms included questions related to their knowledge, attitudes, skills and aspirations (KASA), completed before and after the workshops. The average percentage change in KASA across all workshops was 7.6%. Base knowledge, as evidenced by the pre-course answers, was quite high, and the course led to an improvement in the level of correct answers. However, it was also determined that the knowledge questions were too simple, and the forms have since been updated. Participants in all workshops improved their attitude/confidence in carbon farming and greenhouse gas related topics by an average of 23%, with post-workshop confidence levels sitting between 3–3.5 out of 5 (self rated).

Participants rated overall average satisfaction in the workshop delivery and content as 8.58/10. Over 90% of attendees also indicated their intent to take action following a workshop. When participants were asked what action they would take, common responses included: completing a carbon account; exploring on-farm interventions (cited examples of these interventions were highly dependent on location and production system); further self-educating on the topic or; in the case of advisors, looking for opportunities to support primary producers by offering similar training.

Deliverer feedback

Thirteen advisors were trained as deliverers. Advisors in the first cohort were involved in online train-the-trainer sessions and the delivery of the pilot Carbon EDGE workshops. They reiterated the need for at least two deliverers per workshop to effectively support participants during activities, especially with carbon accounting. The complement of two deliverers also proved useful to be able to cover the material in depth – particularly if one deliverer has expertise in livestock production and the other in carbon farming.

Participants in the second cohort completed a one day in-person training session which they rated 9/10, on average, for meeting their expectations. They will be paired with accredited deliverers to complete workshop delivery as part of their training.

Discussion

Feedback from the pilot workshops reflects a positive response to Carbon EDGE. The results demonstrate the importance of ongoing extension on this subject, with significant scope still to increase confidence levels across the industry and high numbers of participants expressing an intent to take action. The continued success of Carbon EDGE and broader industry adoption relies on several factors:

Delivery model

MLA's EDGEnetwork workshops are typically delivered under a fee-for-service model. With the availability of no-cost or low-cost extension programs – and in some cases a perception that the support for emissions reductions should come from government or supply chain – there was mixed appetite from producers to pay to attend (the pilot workshops were heavily subsidised). This issue would be alleviated if supporting organisations, such as government, industry bodies, NRM groups or corporate agriculture, could provide ongoing subsidies. To secure this type of funding, the program would need to ensure it meets the needs of these organisations, and complements (rather than duplicates) other extension services on offer.

The extension ecosystem

It is likely that complementary models of extension will be required to support on-farm adoption, taking the training knowledge and concepts into the field. This may include, for example, advisor upskilling, long-term practice change programs, grower/producer groups, or the incorporation of relevant information into existing and well-established industry programs (e.g. BMP programs).

Currency

Given the frequency of change and the level of investment in new R&D in this space, Carbon EDGE will require regular updating to remain current. This is particularly pertinent for rangelands environments where less is known about the interventions available to livestock producers to reduce their emissions, and information in Carbon EDGE is lacking (which could further exacerbate confusion and/or low confidence of pastoralists).

It will also be important to reflect developments in Australia's Carbon Market and emerging Nature Repair Market. As methodologies are retired and released, producers will want to understand the options available to them. The possibility for interactions between carbon projects and biodiversity projects are yet to clarified.

Additionally, as new extension programs such as the Federal Government's Carbon Farming Outreach program become available, Carbon EDGE will need to be reviewed to ensure consistent, reliable and accurate information is presented to industry. Engagement with relevant research and extension providers will be essential.

A life in the Central Australian pastoral industry starts here – creating future land managers through Rangeland Management Courses

Kain, AJ[1]; Anderson, GA[1]

[1] Northern Territory Department of Agriculture and Fisheries, Alice Springs

Key words: training; pastoralism; rangeland management; careers

Abstract

The Central Australian Rangeland Management Course (RMC) is a free, one-day workshop that is delivered on-station for new staff. It has been designed specifically for the beef cattle industry operating in arid regions with an extremely variable climate and land capability. The course introduces pasture dynamics, species identification, carrying capacity, cattle nutrition, poisonous plants, weeds and fire management. Participants learn about arid zone ecological processes and climate characteristics that drive pasture production.

The course has a strong practical component and one of the most popular activities involves taking participants into the paddock to find and identify pasture species. Participants also learn how to assess land capability and land condition. For many participants, who are often new to the region, these activities are their first introduction to the plants that form the basis of the grazing enterprise, and they are often amazed at the variety of species.

The first course was conducted in early 2024. Overall, the feedback shows a positive response to the course. Many participants did not feel they had good prior knowledge but found the course very valuable; with the accessibility of the course attracting participants who would not normally attend on their own accord. There has been considerable interest for ongoing connection and support for graduates of the course in the form of WhatsApp groups or a similar platform.

Delivering the courses in a familiar 'home' environment, surrounded by peers, facilitates a positive and relevant introduction to rangeland management. In addition, it introduces people new to the industry to Extension Officers and other professionals they might work with throughout their career.

Introduction

The Central Australian Rangeland Management Course (CARMC) is a free, one-day workshop created by the Northern Territory Department of Agriculture and Fisheries (DAF) designed to upskill early career station hands in Central Australia. It is based on the highly successful Rangeland Management Courses that have been offered on the Barkly Tablelands and the Katherine district for the past 20 years. The courses offer an introduction to pasture dynamics, species identification, carrying capacity, cattle nutrition, poisonous plants, weeds, fire management and biosecurity. However, the northern courses are designed for a pastoral system that is based on a relatively reliable wet season and on extensive, uniform Mitchell grass pastures, quite different to the highly variable climate and landscapes of the arid Centre. With funding from the Northern Western Australia and Northern Territory Drought Resilience Adoption and Innovation Hub (Northern Hub), we customised the Rangeland Management Course to address the unique, environmental challenges of grazing cattle in arid regions.

The course is specifically designed to suit early career station staff. For many participants, this is their first time working in arid Australia. While they bring plenty of enthusiasm and energy to their work, and perhaps some experience handling cattle, they often haven't yet had the opportunity to gain any arid rangeland management knowledge. The course contains lots of practical activities and is designed to be delivered on-station.

Methods

We used the existing RMC as a starting point for designing the Central Australian version. To make it regionally relevant we reviewed the content of existing publications which are aimed at the station management level. The primary resources included the Central Australian Grazing Land Management (GLM) EDGE workshop (Chilcott et al. 2005), various field day presentations designed for Central Australian cattle producers (Kain, pers. comment.), case studies and recommendations from local reports on fire and weed management (Edwards and Allan 2009, DEPWS 2021) and historical documents relating to poisonous plant events in the region. We also took advice from local producers about the information they wanted their staff to know.

While the northern RMC describes a grazing model designed for a relatively predictable wet/dry season, the CARMC needed to describe the fundamental ecology of the arid environment in Central Australia.

One of the strengths of the original RMC is that it is designed to be delivered on-station. On the very large, Barkly properties it is quite common for stock camps to have 10 or more early career staff. It makes sense to train them in a group and on-property, as there is no travel time and the benefits of working with their peers are two-fold; participants are often more relaxed around people they know, and they can share their learnings and experiences after the course. However, in Central Australia, many properties only have 2 or 3 staff which isn't enough to support good group learning. Sometimes it is possible for neighbouring stations to get together and host a course. However, we also had to find a way of getting larger groups together.

Results

Course content

We have created a series of modules using an updated PowerPoint presentation with plenty of practical activities. The Pasture Dynamics module is the first of its kind in explaining the fundamentals of arid Australian ecology and how it relates to pastoral activities to early career station hands.

Our primary focus was to describe the variability of rainfall (within and between years), the importance of understanding 'pasture growth events', the effect of winter rain vs summer rain, how to distinguish between a seasonal rainfall response and land condition, identify different land types and their capability, and identify pasture species (Photo 1) and their grazing value.

Photo 1: Early career station hands use pasture identification guides to identify native grass species and their grazing value.

While most people associate Central Australia with low rainfall, the reality is much more complex and variable. Very high rainfall years do occur, but long periods of low rainfall are more common. When it does rain, almost half the rainy days will occur as isolated occurrences, just enough to settle the dust but not grow any pasture. Hence the concept of *growth events*. Soil moisture levels need to remain conducive to growth for at least a week to stimulate plant growth and germination of new plants. For plants to reach maturity and grow a good bulk of pasture, soil moisture needs to be available for about 4 weeks. In central Australia, this requires at least 60mm of rain and on average, to occur once per summer – critical information for people who rely on pasture growth for their business!

We also discuss the characteristics that make Central Australia pastorally productive. The landscape is old, highly weathered, and often nutrient poor, creating significant landscape variability and areas of low pastoral capability, but also patches of moderate soil fertility. The combination of moderately fertile soil and low rainfall results in plant growth with high nutrient concentration and some of the highest quality pasture in the Northern Territory. In addition, the landscape supports a suite of vegetation that can take advantage of both summer and winter rain, small rainfall events and floods. Building an understanding of landscape function allows us to explain how grazing can influence land condition and ultimately pastoral production.

We have also updated the course to include a module on Biosecurity. In recent years, the pastoral industry has become more acutely aware of the threat of foreign disease incursions into Australia (e.g. Lumpy Skin Disease, Foot and Mouth Disease). It was considered timely and appropriate to include a new module into the RMC syllabus to address this emerging issue and it has been well received.

Table 1: Examples of feedback from Central Australian Rangeland Management Course participants.

'It's okay to take a day away from work, when the course is so interesting and directly relevant to our everyday jobs'.
'I found it interesting how you worked out the amount of grass in the paddock.'
'I'd love to have done this as a first-year ringer – I think it would have changed my perspective on everything.'
'It was useful to identify the weeds and grasses growing out in the paddock.'
'It was interesting to learn about the impact phosphorus deficiency can make to cattle.'
'Working out carrying capacity, forage budget and identifying land types was interesting. Learning about nutrition and how to maintain optimal gut health was a standout.'
'The paddock walk was interesting, getting a better understanding of pastures in the area.'
'Explaining the value of all the different grasses was interesting. Carrying capacity, land condition and how they affect management was useful.'

The course has a strong practical component, well suited to an audience who often choose their career based on a love of adventure and outdoor activity. Perhaps surprisingly, the pasture identification activity is the one that everyone loves the most (Table 1). For many participants, who are often new to the region, these activities are their first introduction to the plants that form the basis of the grazing enterprise, and they are often amazed at the variety of species. We talk about the species that cattle prefer, how grazing can change the pasture composition and what you can do to maintain healthy pastures.

Talking about land condition can be a sensitive subject, but learning how to identify change and the impacts it has on production is important. It is exciting when we go out into the paddock and assess land condition and see the participants analyse how the grazing business and the ecosystem function together. It's one of the things that station managers asked for, to give their staff the skills to distinguish good land condition (desirable, perennial, abundant pasture species) from a flush of green, but short-lived species that won't last long.

Course delivery

Presenting the RMC on-station is ideal because participants get to test their learning immediately on their own country and often the manager will attend too. Ideally, we would have between 8-14 participants however, some stations only have 2 or 3 early career station hands on the property and that would be a very intense learning environment. To ameliorate this, we offer regular courses on the DAF operated Old Man Plains Research Station (OMP). The courses are also offered sub-regionally, for example, in the dining room at roadhouses, so that participants from several stations can gather, see land types familiar to their home station for practical exercises and not have to travel too far.

We have also initiated a program of learning for graduates to keep them informed of current activities and seasonal observations, as well as encouraging them to share their personal experiences around the course content.

Discussion

Being the only truly customised course on pasture dynamics in Central Australia makes this an important addition to livestock production in the region. The realities of long-term rainfall variability and the management implications of discreet growth events are important for pastoral managers and their staff. The human memory is often unreliable and while we certainly remember the very dry years, it's easy to forget that the very good rainfall experienced in recent years is not the 'new normal'.

For managers, this course provides a unique opportunity to train new staff in the fundamentals of rangeland management directly relevant to the station they work on. While the early career staff member isn't likely to be making any high-level decisions about grazing management or cattle health, they are a valuable set of eyes-on-the-ground that become far more useful with increased knowledge. It also helps with job satisfaction, performance, and staff retention when staff understand why they might be asked to do certain jobs and better understand their environment. Participants in the course consistently report that the information they gain is relevant to their daily work, interesting and increases their knowledge.

Offering courses on the Old Man Plains Research Station (OMP) has provided several unexpected benefits. It encourages participants to interact with research and farm staff and learn a bit more about current research projects and results. When the courses are held at OMP, we can offer presentations from other Department of Agriculture and Fisheries staff e.g. Regional Veterinary Officers. Creating relationships between industry support staff and the next generation of land managers leads to beneficial future collaborations. In addition, talking about land condition decline and recovery is often easier to do on neutral ground. This leads to critical thinking and robust discussion about how grazing can impact landscape processes.

Ultimately, some of today's new staff will go on to become the next generation of experienced managers in the Northern Territory pastoral industry. Graduates from the original Barkly Rangeland Management Course from the early 2000's are doing just that and when DAF staff work with them now it's clear that their knowledge and experience of grazing management principles has grown with them (Pettit, pers. comment.). It is hoped that the Central Australian Rangeland Management Course is just the start of a lifetime in the pastoral industry for our next generation of land managers.

Acknowledgements

The customisation of the Central Australian version of the RMC was funded by the Australian Government through the Northern Hub project **Next Generation Land Managers:** Rangeland Management Courses, delivering the first principles of grazing land management to new and emerging Pastoral industry leaders on property.

The authors would also like to acknowledge the contribution of the other members of the broader Northern Territory RMC development team: Ms Stacey Holzapfel, Ms Mary Williams, Ms Caroline Pettit, Ms Jaidyn Eastaughffe, Mr Ben Wirf and the creator of the original course, Mr Chris Materne.

Joint village land use planning across administrative boundaries protects shared grazing lands and water points in Tanzania. Lessons learned from fifteen years of development and policy influencing

Key words: land use planning, pastoralism, pastoralists, rangelands, conflict, policy, Tanzania

Introduction - Context

Land use conflicts are increasing as land pressures grow due to population increase, existing land degradation and access to previously restricted lands is opened. This is particularly the case in pastoral areas often assumed to be ‘free lands’ and where pastoralists are poorly equipped to protect their lands from sale or encroachment with poor tenure security. Where land is taken by government for infrastructural or agricultural schemes, rarely is compensation provided. Appropriate land use planning at different levels – local to national – that considers the needs, interests and priorities of different land users including normally marginalized groups such as pastoralists is needed.

Participatory Land Use Planning in Tanzania

In Tanzania where land and land use planning policy and legislation is relatively progressive, local (village) level, participatory land use planning is formalised through the *1999 Village Land Act No. 5* and the *2007 Land Use Planning Act No. 6*. However, due to a lack of resources and capacity, undertaking VLUP has been slow: in 2016 only 1,640 villages out of a registered 12,788 villages had undergone land use planning (Massey 2016). Where VLUP has taken place, it may not have been done in an adequately consultative way, and particularly when connected to large-scale land investments (Engstrom et al., 2022; Kayera, 2024). Strong gaps and concerns exist in pastoral areas and where land-use conflicts occur, and individual VLUP can fragment shared grazing lands and block movement of livestock between villages (Flintan, 2013; Flintan, 2021).

In 2010 the Sustainable Rangeland Management Project was established (Flintan et al., 2022) originally focused on supporting individual village land use plans, but it soon became clear that where grazing lands were shared across village boundaries a different approach was needed. A review of policy and legislation revealed that the Land Use Planning Act No. 6/2007 (Section 33 (1)(b)) states that where such resources are shared a “resource management sector plan” should be established with bylaws for the continued sharing of resources. To facilitate this plan, the Project supported the development of joint village land use planning, later taken up by ILRI and the CGIAR Livestock and Climate Initiative as part of a bundle of approaches to improve participatory land use planning in pastoral areas (Flintan et al., 2022).

Over the next fifteen years ILRI and partners developed the approach with an independent evaluation (Sulle, 2021) appreciating the support provided to the Tanzania government and a second evaluation highlighting benefits for communities (Waweru et al., 2021).

Today, ILRI and partners are supporting JVLUP across more than 400,000 hectares of village land, which includes approximately 166,000 hectares designated for grazing. This not only benefits village livestock keepers and pastoralists, but also the 100,000 residents gaining from reduced conflicts. In 2024 the JVLUP approach was incorporated into the National Land Use Planning Commission's guidelines on participatory land use planning. This article describes the impact pathways leading to these outcomes.

Outcome impact pathways
i) Developing and piloting JVLUP

Piloting started in four clusters of villages in Kiteto District, Manyara region enabled by a strong international and national partnership. National, regional and district land officers were strongly involved, together with those responsible for grazing lands in the Ministry of Livestock and Fisheries. Ensuring that the process followed government guidance was vital for its success, and for holding up to later scrutiny. JVLUP is an integrated approach bringing together neighboring villages to jointly agree on use of land, based on current land use and land potential. The final plan is a legal document valid for ten years, after which renewal is required.

A clear joint vision and incentives is important to bring together different stakeholders i.e. government and communities want reduced land use conflicts. A sense of collective was established that has held to this day assisted by the shared grazing lands being made up of the names of the villages involves – and led to names such as OLENGAPA (the first grazing land secured) (Amos and Flintan, 2019) becoming 'household' names. Other important factors included ensuring a steady flow of resources through the process (stalling cost us dearly) and working around local and national elections as land (and even the JVLUP process) is an emotive topic and could be used for political persuasions.

In 2022 JVLUP was successfully carried out in two new clusters of villages in Chalinze district, Coastal region. Though the area of these lands was relatively small (totalling under 1000 ha) they now provide a strategic anchor or foothold for pastoralists in the area experiencing increasing land pressures. ILRI and partners are now supporting the application of JVLUP in areas where individual village land use planning has taken place, to explore options for joining up what have become fragmented parcels of grazing lands.

ii) Building capacities to implement JVLUP

The development of JVLUP has been a joint capacity building process for all involved. Trainings were undertaken with and for different stakeholders ranging from conflict resolutions through to necessary financial reporting supported by manuals, learning routes and films. Additionally, community members capacity to protect their lands and defend them in the courts (e.g. in the case of farmer encroachment) has been supported, together with their exposure to decision making forum such as national Livestock Keepers Association meetings (Flintan et al., 2021).

JVLUP was grounded in principles of good governance and gender equity from its inception (Daley et al., 2017) incorporating CGIAR innovations such as community conversations (Bullock, 2024) and women's leadership forums (Dungumaro and Amos, 2019). These strategies have led to significant outcomes, such as over 30% participation of women in decision-making bodies for JVLUP and women's assertive collective actions (Flintan, 2024a).

iii) Influencing the policy environment

The continued success of JVLUP requires an enduring enabling policy environment and has required ongoing engagement with policy actors (Kalenzi, 2016). A key strategy in this regard was supporting engagement and joint learning between land use planners in Tanzania, Kenya and Ethiopia including their joint attendance at international conferences.

In 2022 an MOU Was established between ILRI and the NLUPC. USAID (US$464,487) and the EU (US$450,000) supported the Tanzania Natural Resource Forum to expand the approach. And in 2024 a national guideline on joint village land use planning was launched, with the validation workshop officiated by the Deputy Minister of Lands, Housing and Human Settlements Development Hon. Geoffrey Pinda (Flintan, 2024b).

Conclusions

Influencing policy through the technical development of an innovation that serves the interests of multiple stakeholders across a nation is challenging, takes time and needs a strong cross-sectoral partnership. It took a decade and a half from the initial joint village land use planning innovation idea, to then being piloted, validated and finally incorporated into the national guidelines. The final challenge, and the biggest one we face now is implementing the approach at scale, with continued limited government allocation of resources to the approach despite increasing land use conflicts.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Toward a new methodology for conceptualizing mobile pastoralists' and pastoralist women's tenure and mobility rights

Kroeker-Maus, D[1]; Davila Pereira, I[2].

[1] Rights and Resources Initiative; [2] Rights and Resources Initiative

Key words: community-based governance; land rights; pastoral livelihoods

Abstract

Despite the global importance of mobile pastoralism to rangelands management, the mobility and tenure rights of pastoralists remain under-recognized and undervalued in policy and practice. This paper proposes a comprehensive methodology to assess the security of pastoralists' mobility and tenure rights, using a framework grounded in community-based tenure regimes (CBTRs). The framework considers mobility, access, use, management, participation, and exclusion rights, and proposes indicative indicators—both positive and negative— to evaluate the extent to which laws, policies, and customary practices uphold or undermine these rights. The framework also assesses the specific rights of women across three domains: mobility and land access, livelihoods and resource use, and governance participation. By integrating legal analysis and community-level insights, this paper provides a pathway for nuanced, comparative assessments of pastoralist systems, fostering equitable and sustainable policy interventions.

Introduction

There are as many as half a billion pastoralists worldwide, and an estimated 1.3 billion people who benefit from pastoralist value chains (World Bank, 2021). Rangelands cover more of the earth's surface than any other land use type, and pastoralism forms the basis of community livelihoods in over 100 countries, on all inhabited continents (Manzano et al, 2021). The United Nations Environment Programme has identified Pastoralism and rangelands as globally significant, but under-recognized and undervalued (Johnsen et al, 2019).

Mobility is central to the livelihoods, cultural identity, and climate adaptation strategies of Pastoralists and Mobile Indigenous Peoples, and includes social, political, economic, and philosophical and religious dimensions (Hempstead and Rodgers, 2023). Despite its critical importance, mobility is often neglected or actively suppressed in national and regional land-use policies, through measures such as forced sedentarization (Semplici and Rodgers, 2023). Such restrictions on mobility have historically inflicted severe impacts on pastoralist communities, with especially adverse effects on women, who are typically the holders of community knowledge and traditions (See e.g. Kaur et al, 2023. Balehey et al, 2018). Furthermore, restrictions on mobility contribute to environmental degradation through overgrazing, and impair pastoralists' ability to adapt to shifting social and environmental conditions (Messmer et al, 2024; Elias, 2023; Liao et al, 2020).

This paper proposes an indicative methodology for conceptualizing and analysing the robustness of pastoralists' mobility and tenure rights. Here, "mobility rights" are understood both as a distinct category of rights, directly affecting the ability of these communities to move seasonally, and as a defining characteristic of other rights, influencing their recognition and realization beyond a fixed area, thus impacting the security of community mobility.

In this paper, we understand pastoralism as a livelihood system primarily based on the extensive management of domesticated animals, characterized by mobility as an adaptive strategy to optimize resource use in variable environments. It involves the close relationship between people, livestock, and landscapes, typically guided by traditional ecological knowledge and social institutions that ensure sustainable use of common-pool resources. Pastoralism encompasses culturally embedded practices that rely on communal or shared land tenure systems.

Tenure rights are conceptualized here using a bundle of rights, drawing on Schlager and Ostrom (1992) and similar methodologies developed by the Rights and Resources Initiative (RRI). The present methodology applies the same unit of analysis as other RRI tenure tracking analyses: the Community-Based Tenure Regime (CBTR), defined as the set of national and state-level laws and regulations governing situations in which rights to terrestrial natural resources are held at the community level. Here, the CBTR concept extends to laws and regulations governing all situations in which the rights of use, movement, and access of mobile pastoralists are collectively held. Critically, this analysis also considers whether rights are static – that is, inhering only to a fixed area of land – or dynamic, inhering to the community itself and thus applicable across their annual migratory routes.

Proposed Methodology

The methodology proposed here identifies two broad, interrelated sets of bundles of rights as areas of assessment. The first is a bundle of mobility and tenure rights held by pastoralists at the community level. The second is a cross-cutting bundle of the specific rights of women within pastoralist systems, which is elaborated in the following section. Each area of analysis identifies key issues and indicative indicators, offering a baseline that facilitates cross-contextual comparison while allowing for context-specific tenure and mobility arrangements in different jurisdictions.

The areas of analysis at the community level include: Mobility and Access Rights; Use and Management Rights; Participation and Exclusion Rights.

Mobility and Access Rights:

Legal recognition of mobility, such as through bilateral and regional transhumance protocols or national policies, forms the baseline for analysis. Barriers to mobility include land-use conversion, infrastructure development, and conservation policies that conflict with traditional pastoralist corridors. Similarly, access rights hinge on whether pastoralists can legally and practically access resources seasonally or communally. The framework evaluates recognition of overlapping and reciprocal access rights, distinctions between human and livestock access, and provisions for cross-border access. Positive indicators for these rights include legal protections for mobility, frameworks for customary and seasonal access, and recognition of Free, Prior, and Informed Consent (FPIC) (Hempstead & Rodgers, 2023; Davies, 2024). Negative indicators include sedentarization policies, inconsistent infrastructure planning, and the criminalization of mobility.

Use and Management Rights:

The sustainable use and governance of rangelands, water points, and other critical resources are foundational for pastoralist livelihoods (Natural Resources Institute, 2017). This framework evaluates the extent to which pastoralist resource use is legally protected, whether for subsistence, commercial, or cultural purposes. Barriers such as fees, permits, or procedural restrictions are analyzed alongside provisions for community-based resource management.

Positive indicators could include the presence of legal protections for different resource use types, state investment in pastoralist infrastructure, and mechanisms for joint resource management. Negative indicators include procedural restrictions on resource access and incidences of conflict.

Participation and Exclusion Rights:

Pastoralists' participation in land-use planning and decision-making processes is a critical component of equitable governance. The analysis includes consideration of legal provisions for FPIC, representation in governance bodies, and the inclusion of pastoralists in national and regional policy frameworks. Exclusion rights are understood as pastoralists' ability to regulate and negotiate third-party access to their grazing lands (See Hempstead & Rodgers, 2023; Robinson et al, 2017). Positive indicators include robust participatory mechanisms, legal requirements for FPIC and provisions for communal land governance. Negative indicators include unilateral state actions that undermine pastoralist mobility without consultation, and the use of enclosures.

Gender and Women's Rights

In addition to rights held at the community level, the framework also considers the specific rights of women within pastoralist tenure systems through three interrelated areas of analysis: Women's Mobility and Land Access Rights; Women's Livelihoods and Resource Use; and Women's Governance Rights. Within each of these areas of analysis, we also propose indicative indicators

Women's Mobility and Land Access Rights

Indicators of progress include gender-sensitive laws that ensure equal mobility rights and access to safe infrastructure like water points. Barriers include laws or regulations restricting women's independent movement or rights to land.

Women's Livelihoods and Resource Use

Positive indicators include legal recognition of women's rights to own or co-own livestock, women's specific rights to access water and pasture, and their equal inheritance rights. Negative indicators include restrictions on women's livestock ownership or control of income from livestock production.

Women's Governance Rights

Positive indicators include established quotas or minimum participation thresholds for women in community executive and decision-making bodies, and quorum requirements for binding resolutions or votes. Negative indicators include exclusionary practices such as requiring male consent for women's participation.

Discussion and Implications

This framework offers a novel contribution to understanding and evaluating the mobility and tenure rights of pastoralists, a globally significant but under-recognized system of livelihoods. By applying the concept of a bundle of rights within the context of transhumance, it bridges critical gaps in existing analyses of rangeland governance and mobile pastoralist rights.

Through a consultative and collaborative process, RRI proposes to operationalize this framework in diverse pastoralist landscapes by applying the methodology across regions and refining indicators to better capture nuanced dynamics. Policymakers and advocates can use these global insights to strengthen governance systems and support the equitable development of pastoralist communities in the face of mounting environmental and socio-political challenges.

XII INTERNATIONAL RANGELAND CONGRESS
AUSTRALIA 2025

Documentary film - stories of American rangelands: meeting the challenges of a changing climate & culture

Hutchinson, B[1,2]; Audoin, F[1,3]

[1]School of Natural Resources and the Environment, University of Arizona

[2]IYRP Global Coordinating Group; North America IYRP Support Group; & Rangelands Partnership, Tucson, AZ, USA 85718.

[3]Rangelands Partnership & Society for Range Management. Environment & Natural Resources 2, N354. 1064 E. Lowell St., Tucson AZ, USA 85721

Key words: IYRP North America; film; outreach

Abstract:
In honour of the International Year of Rangelands and Pastoralists (IYRP2026), members of the North America IYRP Support Group and the Rangelands Partnership initiated an effort to produce a feature-length documentary film about North American rangelands. This documentary, to be premiered in 2026, focuses on their importance for meeting 21st Century environmental, cultural, and economic challenges; and specifically, reducing the effects of climate change (https://www.iyrp.info/north-america/film-projects/documentary-film). Storytelling is the vehicle used for highlighting the historic and intrinsic values of these lands within the context of indigenous knowledge and current science. The long-term goal is to change public perceptions, notably held by urban populations, policymakers, and youth, regarding the value of these lands and the need to conserve them. By presenting real-life stories about the people whose livelihoods depend on these lands, viewers will learn about new technologies for land management, collaborative conservation efforts, and the many ecosystem services provided by rangelands. These include food and fibre production, clean water, wildlife habitat, wildfire control, carbon storage, renewable energy, and recreation. With input from the film's Advisory Board, overall themes were identified:

1. Rangelands and pastoralists defined.
2. History of rangelands and their management including Native American perspectives.
3. Climate solutions:
    a) Soils/carbon sequestration, extensive vs. intensive agriculture, land fragmentation issues.
    b) New technologies & strategies, i.e. virtual fencing, drones/remote sensing, regenerative grazing.
    c) Ecosystem services: food and fibre production, clean water, wildlife habitat, recreation, wildfire control, and renewable energy.
4. Connecting people to rangelands; keeping working lands "working"; how we can help protect our rangelands.

Landmark Stories, an award-winning filmmaking team based at the University of Arizona, is producing the film (https://landmarkstories.arizona.edu/). This team has experience in documentary storytelling on natural resources themes and also positive working relationships with members of the IYRP coordinating groups and the Rangelands Partnership.

Introduction

Rangelands occupy 54% of all land on Earth (UNEP 2014) and at least 30% of land in the United States (NRCS 2024) and are home to an estimated 200 million people worldwide. Yet, people from urban areas are often disconnected from the importance of rangelands to their health and wellbeing. The mission of the International Year of Rangelands and Pastoralists (IYRP2026) is to promote an understanding and appreciation of rangelands around the world, the people who manage them, and their contributions to all communities. In North America, rangelands are particularly important for livestock production, wildlife habitat, and recreational activities as well as valuable sources of clean water, carbon storage, fresh air, open space, and renewable energy resources. As important as rangelands are, they are increasingly impacted by land fragmentation, residential encroachment, and cultural change that divide these landscapes into less functional ecosystems and impact their ecological and economic opportunities. Furthermore, misconceptions about rangelands are numerous. Some people may see them as wastelands that make little, if any, contribution to public needs, while others consider all livestock grazing as detrimental and leading to irreparable degradation. However, these views are not supported by either current science or day-to-day experience. The IYRP2026 presents a unique opportunity to highlight the incredible value of rangelands to the people and communities that rely on them while at the same time helping focus attention on the challenges and potential consequences if these vital ecosystems and pastoralist communities are lost. To reach out to the public with these messages, the North American (NA) IYRP Support Group and members of the Rangelands Partnership initiated an effort to produce a feature-length film about North America's rangelands focusing on real-life stories about the people whose livelihoods depend on these lands and the nature of their stewardship. Highlights include new technologies for land management, collaborative conservation efforts, and the many ecosystem services provided by rangelands.

Methods

An initial research phase found considerable evidence that the medium of film can reach millions of people quickly and effectively (Filbin 2020; Schimmel 2021; Veritzman 2023) and that documentaries, specifically, are often used as teaching resources from grade school to higher education (Vaughan-Lee 2024). Thus, it was determined to pursue this means for bringing attention both to the promise of American rangelands and to the IYRP2026. From the start, multiple groups and individuals have been directly involved in producing the film. The Landmark Stories Production Team is an award-winning filming crew based in the Cyber and Communications Technologies Lab at the University of Arizona (https://landmarkstories.arizona.edu/). This team has experience and expertise in documentary storytelling on natural resources themes and positive working relationships with members of the film's many advisors. The Project Team of advisors includes four groups who represent various aspects of rangeland science, education, and outreach. (1) The Rangelands Partnership is a 25-year collaboration of rangeland extension professionals (providing non-formal science-based education and learning activities), science librarians, and information technology experts from 19 Western and Great Plains Land Grant universities. The Partnership's primary product is the Rangelands Gateway (https://rangelandsgateway.org). (2) The IYRP NA Support Group is composed of more than 50 rangeland experts from three countries, all committed to assisting with IYRP outreach initiatives. (3) The Western Association of Agricultural Experiment Station Directors (WAAESD) is one of five regional organizations that plan and manage multistate research activities throughout the U.S. Its membership includes university deans, directors, and administrative officers. (4) Lastly, the film's 30-member Advisory Board is made up of rangeland science experts, filmmakers, and members of IYRP coordinating groups. The Advisory Board has been integrally involved in guiding and reviewing progress in the film's development. The full Project Team represents a cross-section of key stakeholders from diverse backgrounds and perspectives. At the same time, members have direct linkages with the most current science, innovative educational programming, and inspiring storytellers with practical knowledge and experiences to share.

The initial phase in the development of this film project was an ambitious fundraising effort. Through WAAESD, early contributions were received by land-grant universities and individuals. However, reaching the goal of $300,000 has proved to be elusive so the project coordinators began submitting proposals wherever appropriate. Grants were received from the U.S. Department of Agriculture's Renewable Resources Extension Act and the National Grazing Lands Coalition, and other grant opportunities are being evaluated at the time of this writing. A description of the production phases follows:

Phase 1: Pre-production (initiated January 2024) – directors and writers a) research and explore themes; b) gain input from Project Team members at multiple stages of story development; c) determine best approach for gaining the broadest exposure, i.e. potential locations and interviewees; and d) create a compelling narrative that informs about big issues through personal stories.

Phase 2: Production (Summer 2024 through Spring 2025) – a) review themes with all partners and producers; discuss ideas and options for the most relevant and compelling stories that align with the overarching theme of "climate change;" b) determine and finalize list of locations, characters and actions for each scene to be filmed; c) create a working shot list for each scene; d) determine and secure production crew and their availability; review production gear requirements and requests based on the story treatment; e) review and adjust shot list with the Director of Photography; incorporate partners and producers' visions into the treatment of scenes and overall visual style; f) determine schedule for travel to the selected locations, confirm interviews and actions to be filmed; secure travel and lodging for film crew; and g) commence filming and continue until completed.

Phase 3: Post-Production (Summer 2025 – Winter 2026) – a) film editing commences until a rough cut is achieved; b) sound mixing, design, effects, and musical soundtrack edited by Sound Designer in cooperation with Editor and Director; c) computer graphics, maps, after-effects, and motion effects created by the Graphic Designer in cooperation with the Editor and Director; d) rough cut is submitted to partners and key stakeholders for review and feedback; the post-production team digests and addresses partners' comments and suggestions and makes any necessary changes; e) trailer is finalized and distributed to partners and key stakeholders for review and feedback; the post-production team digests and addresses partner comments and suggestions and makes any necessary changes; and f) film and trailer are finalized for final review by partners and key stakeholders; changes made, if necessary and possible.

Phase 4: A fourth phase for an "**impact campaign**" will include marketing activities, a launch event, press release, and a guide for viewers and educators. Members of the Project Team have already agreed to publicize the film through their regular programming activities and social media outlets and will track results as part of an assessment of the film's impact. The projected release date is tentatively scheduled for March 15, 2026.

Based on input from all Project Team members, the following themes and sub-themes were determined as the preliminary approach for the film's stories.

1) Rangelands and pastoralists defined drawing on imagery from North America.
2) Historical summary of rangelands and their management in the context of Native American perspectives.
3) Climate solutions:
    a. Soils/carbon sequestration, extensive vs. intensive agriculture, fragmentation issues.
    b. New technologies & strategies, i.e. virtual fencing, drones/remote sensing, regenerative grazing.
    c. Ecosystem services: food and fibre production, clean water, wildlife habitat, recreation, wildfire control, and renewable energy.
4) Connecting people to rangelands; keeping working lands "working"; how we can help protect our rangelands.

Film has been proven to be an effective medium for influencing people's attitudes in a constructive way (Kashani 2016; Kubrak 2020), and specifically for understanding and engaging people round the issue of climate change (McGreavy & Lindenfeld 2014). However, while there are many videos on YouTube on a variety of aspects of climate change and rangelands, most are quite short, tend to be academic, and have had a limited number of views. An extensively marketed and distributed feature-length film provides a unique and possibly game-changing opportunity to grab the attention of people at a national, and even international, level to inform and influence their perceptions and understandings of the importance of rangelands.

The first media product of the film project will be a trailer that will be posted on YouTube and other social media outlets to build interest in the feature film. A preliminary trailer will be provided to the members of the film's Advisory Board, the NA IYRP Support Group, and members of the Rangelands Partnership for review and comment. After receiving this input, the trailer will be finalized and distributed along with a "Guide for Use" and a brief viewer survey to identify any new perceptions identified after the release of the film. Project members will be requested to show the trailer to their constituencies during extension-focused events such as workshops and seminars, as well as with marketing the trailer and the film's date of release. The trailer, along with a "Coming Soon" announcement, will also provide the means for promoting the film to independent theatres and to public television. A similar marketing and distribution process will be undertaken and documented when the feature-length film is nearing completion towards the end of 2025. Additionally, it is expected the film will be entered in various film festival competitions such as Jackson Wild, Sundance, and Telluride Mountain Film Festival.

Results

The long-term goal is to change perceptions of the public, particularly new audiences such as youth and urban populations as well as policymakers, regarding the value of rangelands and the need to conserve them. Post-viewing surveys will be made available after selected viewings, particularly those presented at independent theaters, and on social media outlets. By presenting real-life stories about the people whose livelihoods depend on these lands and the nature of their stewardship, viewers will learn about innovative new technologies for land management that can contribute to climate solutions, collaborative conservation efforts, and the many ecosystem services provided by these lands to people across the continent and throughout the world.

Discussion

The target audience is the general public, including agricultural producers, educators, students, and recreationists, both from urban and rural areas. In addition, a major focal group will be agency personnel and policymakers as many of the film's themes are relevant to current policies. To address the profound impacts of climate change at environmental, economic, and social levels, a greater understanding of the role of natural resources, specifically rangelands and grasslands, is needed if their potential as a climate solution is to be realized. To this end, the film will have the possibility of widely and positively influencing collective action to increase climate resilience. Through real-life stories, our target audiences will have new information that can lead to an improved understanding of rangeland ecosystems, technological processes, and promising management technologies and strategies to reduce the effects of climate change.

Acknowledgements

As noted above, many people and organizations have provided intellectual and financial support for this documentary film. Financial contributors are noted on the IYRP documentary film webpage - https://www.iyrp.info/donations-received. In addition, individuals serving on the Advisory Board as well as members of the Rangelands Partnership have provided considerable help in identifying key people to interview throughout North America. Finally, approvals were obtained from the University of Arizona Human Subjects office for conducting interviews and guiding the process for obtaining consents.

ESRM Planning, delivering NRM action and direction through collaboration

Marver, RA [1]; Hyatt, JC[1]

[1] Contour Environmental and Agricultural Consulting, Northcliffe Western Australia

Key words: NRM; Rangelands; WA; Collaboration; Landscape.

Abstract

The Ecologically Sustainable Rangelands Management (ESRM) process has evolved over the past 17 years, from a federally funded Western Australian Natural Resource Management (NRM) project to a commercial service available to land managers across the Australian rangelands. At its core is collaboration and innovation to deliver positive NRM outcomes for areas that are subject to multiple management motivations. To date, the process has delivered over 120 management plans for areas under pastoral, mining, indigenous and conservation management. The plans represent over 23,200,000 hectares in Western Australia (WA) alone, which equates to 10% of WA rangelands and 27% of the WA pastoral estate. ESRM is now the dominant environmental planning process within the WA rangelands, and the program is being extended to other states.

Grounded in science, the process maps and documents a land manager's own ideas and goals for the management of an area, and devises strategies and activities to help them achieve those goals, while maximising the positive NRM outcomes for the area. Where stakeholders have conflicting management ideas and goals, the process allows for frank discussions and identification of commonalities to generate a strategy that provides a sound compromise for all, whilst working within accepted best practice NRM frameworks. The process incorporates well-proven rangelands management with emerging technology to deliver a whole-of-landscape plan that is practically implementable.

This paper will outline the ESRM process, and how it promotes a collaborative approach to sustainable land management to maximise positive NRM outcomes while improving productivity and profitability.

Introduction: The evolution of ESRM

The rangelands of Western Australia (WA) encompass much of the arid and semi-arid zone, and accounts for approximately 87% of the state's total area (DPIRD 2022). Approximately 39% of the rangeland area consists of Crown land pastoral leases (DPIRD 2022), which are leased to pastoralists and gives rights to graze authorised livestock on the natural vegetation (Government of Western Australia 2023). The rangelands have seen extensive modification to the landscape function, soils, flora and fauna as a result of the long history pastoralism, particularly of sheep and cattle grazing (Brandis 2008). The pastoral industry contributes significantly to our economy however a legacy of significant environmental degradation from prolonged overgrazing since the mid 1800s remains to this day, from which many parts of the landscape have not fully recovered (e.g. Burnside et al. 1995; Alchin 2011; Tinley and Pringle 2014).

In January 2000, the federally funded Ecosystem Management Unit (EMU) extension program was initiated as part of the Gascoyne-Murchison Strategy, underpinned by the concepts of ecological management and biological conservation. This extension program involved over 120 properties from the Carnarvon coastal plain and Gascoyne, Murchison, and north-east Goldfields to the Nullarbor over a period of seven years before federal funding was terminated in 2006 (Tinley and Pringle, 2012 Pers. Comm.). A short time later, the Department of Agriculture and Food WA (now Department of Primary Industries and Regional Development (DPIRD)) established the Ecologically Sustainable Rangelands Management (ESRM) extension program, with its foundations and approach based on the EMU extension program, and an aim to improve the profitability and productivity of rangelands enterprises by improving grazing systems, resource sustainability and conservation (Tinley and Pringle, 2012 Pers. Comm.). Over a period of four years the ESRM program covered 40 stations in the Gascoyne, Carnarvon coastal plain and Pilbara.

These extension programs have demonstrated that improving productivity and profitability and maximising positive NRM outcomes can be achieved simultaneously. As the saying goes, ‘Look after Country, Country will look after you’ (Weir et al. 2011). If we are to minimise adverse impacts to the environment well into the future, we must continue to engage and collaborate with land managers and provide them with the knowledge and tools necessary to maximise positive NRM outcomes in such a way that also protects their bottom line. In recognising this, Contour Environmental and Agricultural Consulting have refined and developed the ESRM process into a commercially deliverable service. The process is highly adaptable with respect to location and the ability to integrate the findings of relevant scientific research and technologies, and broadly involves: a preliminary desktop assessment; a facilitated property visit involving the lessee/property manager; and the development and delivery of the ESRM Plan. To date, the process has delivered over 120 management plans for areas under pastoral, mining, indigenous and conservation management. The plans represent over 23,200,000 hectares in WA alone, which equates to 10% of WA Rangelands and 27% of WA Pastoral Estate. The service has been in constant demand in WA and is now being extended to South Australia, which is a testament to both the successful track record and adaptability of the ESRM process.

The ESRM Process

Preparing for an ESRM property visit

In preparing for an ESRM property visit a preliminary desktop assessment of the subject property is undertaken. With permission from the station’s lessee, any government-held information and spatial data relating to the property is accessed and examined, such as previous rangeland condition assessments, rangeland monitoring system and pastoral monitoring sites. Spatial infrastructure data and land system and/or vegetation mapping is used to prepare paper-based maps for markup during the property visit. Long-term median rainfall figures are compared to figures from the past 20 years to gain a more accurate understanding of more recent rainfall patterns, and the implications this has for land management and stocking decisions on the ground. A cumulative rolling rainfall graph benchmarked against the median rainfall for the subject station is created, with indicative cues for adjusting stock numbers based on the amount of rainfall received, relative to the median. This is presented to the land manager during the property visit as an additional tool which can be used to assist in making stocking decisions.

ESRM property visit

Discussions with the lessee typically commence over the prepared paper-based maps and a cup of tea. This serves several purposes; it facilitates open discussion, allows mapped spatial data to be checked with the land manager for accuracy, highlights areas of interest which will give direction to the inspection of the property, and starts to ‘build the story’ to be told in the ESRM plan. The lessee is asked to draw out: current tracks and infrastructure present and state of repair/disrepair; stock numbers and distribution across the property; mustering areas; productive/overutilised grazing areas; areas of conservation or cultural significance to the lessee; and areas with specific issues or concerns such as track erosion, scalding, fire, weed invasion, stray cattle/feral herbivore ingression. The lessee is also asked to map out planned future works for the lease, such as infrastructure or conservation areas, including any ‘wish list’ items which fit with their overall production and NRM goals for the lease. Existing alternative enterprises occurring within the lease, or opportunities for potentially suitable alternative enterprises (such as carbon farming projects or eco-tourism, for example), are also discussed. This ensures that all aspects are captured to develop a cohesive ESRM plan, where recommended future management activities are complementary and aligned with the lessee's goals for the property.

Depending on the size of the property, an inspection is undertaken ideally over a period of days. For both parties, maximum benefit is derived when the lessee is present for the inspection with the facilitator. This allows for any issues or concerns raised during the mapping exercise to be ground-truthed and explored in-situ. Potential remedial actions can also be considered in a specific context and how they may be implemented. Potential Case Study Areas are selected from points of interest traversed during the inspection, with the intention that remedial actions be trialled at a small scale with minimal investment of resources, and then applied to other areas of the property if proven successful or revised if unsuccessful. There is also opportunity for the facilitator to raise issues or concerns which the lessee may be unaware of. The scale of some issues which affect landscape condition and function, such as erosion, may not be obvious or visible from the ground, and may not even be occurring from a trigger point on the subject property, in which case there may be a need to address the issue at a larger scale over multiple properties, or the wider catchment. In the past aerial surveys of a property were often undertaken by plane or helicopter to cover large areas in a short amount of time, however the risk exposure and costs associated with this method can be prohibitive. With recent advancements in technology, aerial surveying has become far more accessible and efficient through the use of drones, which are becoming an increasingly powerful tool for landscape assessments. Characteristics of the vegetation and landscape condition and function are noted and photographed on the ground and by drone where appropriate during the inspection. Global Positioning System (GPS) coordinates and photographs are also taken at waterpoints and points of interest, which may include areas experiencing issues with erosion, overutilisation/underutilisation, productive/unproductive areas, fire-affected areas, and conservation or other areas of cultural significance to the lessee. Covering as much ground as possible in the allotted time is desirable for developing a robust whole-of-landscape ESRM plan.

Development and Delivery of the ESRM Plan
The ESRM plan is a synthesis of all information collated prior to the property visit and of the discussions, photographs and GPS points collected during the property inspection. It then presents suggested remedial management actions and strategies, tailored to the circumstances occurring on the property. The plan assigns a suggested priority and outlines a timeline for implementation based on the land manager's current situation and aspirations. Case Study Areas selected from the property inspection are mapped and annotated images are marked up to outline the current situation, and the proposed works needed in these specific areas to remediate the issue. Remedial works are described in detail and approximately costed to give the lessee an indication of the investment required.

The plan also captures the lessee's current land management strategies relating to grazing, stocking rate and fire where applicable, and introduces proposed strategies for each, while giving consideration to future plans for the property. This ensures that management strategies are not temporally restricted in their application. A key focus of the ESRM process is to develop a proposed grazing and stocking strategy that puts rainfall into context of the carrying capacity for the property in its current condition. Carrying capacity estimates are made for the entire property and individual paddocks/grazing areas, based on the land systems/vegetation in their current condition, and are converted to stock days and a recommended stocking rate per 10 or 100mm of rainfall, which has been benchmarked against the median rainfall for the property.

Any alternative enterprises discussed during the property inspection are worked into the overarching strategy for the property. If alternative enterprises, such as carbon farming for example, have not yet been implemented but are being considered by the lessee, an assessment is undertaken and commentary made on the suitability and feasibility of such an enterprise.

Fire is a natural and important part of landscape ecology. Where fire management on a property is necessary, the proposed management strategy breaks the property into fire management zones, which are allocated a burn order or are designated no-burn areas, based on their position in the landscape and other management priorities for the property. Land managers are encouraged to engage with the regions' Indigenous Ranger groups, or other Indigenous groups with connection to the land by way of Native Title, to support them in fire management capacity building.

A proposed monitoring programme and monitoring schedule is provided to the lessee, which includes specific locations where photographs and condition changes should be repeatedly recorded, and at what time intervals, to track the success or otherwise of any remedial works undertaken.

After being reviewed and agreed upon by the lessee, the final ESRM Plan is delivered along with a poster which summarises the proposed works outlined in the ESRM Plan. Displaying the poster in a visible location increases motivation to implement the proposed works, and is a quick way to cross-check works completed and those yet to be completed.

Conclusion

A primary goal for pastoralism is about managing a '…profitable livestock business, while maintaining the land and vegetation in good condition' (DPIRD 2022). This is no easy feat, given that many pastoralists are already managing the rangelands under challenging and often unfavourable conditions. Many are still suffering to some extent from the consequences of historical overgrazing by sheep and cattle over many decades, while also contending with the effects of a highly variable climate, such as prolonged periods of drought. It is essential that pastoralists continue to be provided with the tools and up-to-date knowledge necessary to achieve their goals and to make the best decisions for managing their business and land in a sustainable way; the ESRM process is one such way this can be achieved. The ESRM process promotes a much-needed collaborative approach to sustainable land management, bringing pastoralists, ecologists and other field experts together to maximise positive NRM outcomes while improving productivity and profitability.

[3] College of Community Science, UAS, Dharwad-580005, Karnataka, India

Key words: Rainfed Cultivation, Drought Tolerance, Market Volatility, Anantpur, Seed price

Abstract
This study examines the trends and factors influencing Stylosanthes seed production in Anantapur district, Andhra Pradesh, a region characterized by arid conditions and low rainfall. The area under Stylosanthes cultivation increased significantly from 2011 to 2020, driven by its drought tolerance and suitability for rainfed lands. However, irrigated areas declined as farmers opted for more lucrative crops. Seed production showed a seven-fold increase, while seed yield and selling price exhibited minimal and volatile changes, respectively. The study highlights the importance of policy support and technological improvements to stabilize and enhance Stylosanthes seed production. Market volatility and government demand fluctuations were identified as key factors affecting seed prices. Overall, the research underscores the potential of Stylosanthes as a resilient crop for arid regions.

Introduction
Seed is the most critical input to enhance the production potential of all agricultural crops, including fodder. In India, fodder is produced from 8.34 million hectare of cultivated and 10.39 million hectares of permanent pasture. Fodder yield from these lands is lower than the potential yield and the availability of good quality seeds are estimated to be around 15-25 percent only for cultivated forages (Chauhan et al, 2017). Availability of quality seed is vital because the forage crops have been bred for enhanced vegetative potential as they are shy seeders with very low seed productivity. Therefore, assured supply of fodder seed of improved varieties/hybrids to farmers at reasonable price is crucial for enhancing fodder production.

Stylosanthes is a legume fodder crop rich in crude protein that can be cultivated as grassland or pasture. Animals can feed on it directly. It is adapted to tropical climates and tolerant to low fertility, drought, acidic soils and poor drainage. The highly palatable *Stylosanthes hamata* species is preferred by animals. In India, Stylosanthes seed production started during the late 1970s by government departments. In the mid 1980s small farmers in the Rayalseema region, Ananthapur district in Andhra Pradesh, started Stylosanthes seed production to meet rising demand from government agencies for their wasteland development programs. Some farmers from the Palasamudram village in Ananthapur were trained in Stylosanthes seed production at the Raddipalli state farm of the Department of Animal Husbandry and Veterinary Services (Rao 2004). Over the years the improved seed production technology spread to surrounding villages through farmer-to-farmer exchange of seeds and technical knowledge. Stylosanthes seed production today is largely concentrated in three mandals of Hindupur and Penukonda Division of Ananthapur district comprising a network of 40–50 villages (Biradar et al, 2013). So, seed demand for this crop is met predominantly by farmers which is not so in other crops. Farmers as seed producers of Stylosanthes are concentrated in the Ananthapur district of Andhra Pradesh and over the years this crop emerged as an important crop of the region. These aspects which provide entirely different scenario as compared to other crops intrigued researchers to understand the current production and the trend of this economically important crop of this arid region.

Methodology

Ex-post facto research design was used. This design was considered as appropriate because the phenomenon of Stylosanthes seed production by farmers has already occurred. The Research study was conducted in Hindupur region of Anantapur district of Andhra Pradesh state, as Stylosanthes seed production is predominantly carried out in this region. Three blocks viz., Gorantla, Chilamathur and Somandepalli were selected based on earlier studies conducted by ICAR-IGFRI, Jhansi where Stylosanthes seed production is practiced predominantly. TFour villages having maximum area under Stylosanthes cultivation were selected from each block. In total, 12 villages were selected. They were Gollapalle, Palasamudram, Vadigepalli and Mallapalle from Gorantla block, Settipalli, Kodikonda, Morasalapalli and Reddicheruvapalli from Chilamathur block and Bramhasamadram, Edulabalapuram, Chalakur and Julukunta from Samandepalle block. From each village, ten respondents were selected randomly, constituting a total sample size of 120. A structured interview schedule was developed by consulting experts and referring to the relevant literature. Pretesting of the schedule was carried out in a non-sample area for its practicability and relevancy. The final schedule was prepared by making necessary corrections based on pre testing results. The primary data was collected from the farmers through personal interview method in an informal atmosphere. Data was analysed using a compound growth rate analysis method.

Results and Discussion

Percentage change in Stylosanthes area cultivated by the respondent from 2011-2020

The total area under Stylosanthes cultivation by the respondents was 58 acres in 2011 and increased to 377 acres in 2018 and remained same till 2020 (Fig 1). Average annual increase in area was 55 per cent while compound annual growth rate of area under Stylosanthes was 28.46 per cent. Stylosanthes is a very hardy crop. It is credited with very high drought tolerance and is almost free from pests and diseases. The study area is characterized by very scanty and low rainfall, consisting of an arid and treeless expanse with poor red soils. Anantapur district is the second driest district in the country, after Jaisalmer district in Rajasthan. The average annual rainfall here is just 520 mm, which is the lowest in Andhra Pradesh and the second lowest in India.. Rainfall distribution is erratic, uneven, and irregular throughout the year. The study area is deprived of both the monsoons and subjected to seasonal drought. Variations in climate, in terms of temperature and rainfall, have become more and more evident in the last decade. Challenging weather accompanied by changes in climate parameters might have led respondents to increase the area under Stylosanthes in rainfed lands.

However, there is a decline in the irrigated area under Stylosanthes. Stylosanthes cultivation in irrigated areas was just 20 acres in 2011 and reduced to 8 acres in 2020. The availability of groundwater enhances the opportunity to grow varied crops. Farmers might have cultivated commercial and more remunerative crops like groundnut, maize, etc to obtain more income under irrigation. In addition, the price of Stylosanthes seed depends on demand from government agencies and, thus is volatile. Farmers of irrigated areas might instead grow those crops which would fetch them more stable price. This might be the reason for the decline of irrigated area under Stylosanthes.

A similar study by Biradar et al (2003) reported that the first survey taken up in 2002-2003 showed increase in area and the second survey taken up in 2012 to document changes in area from 2002-2012 showed decline in the area asthe purchase of Stylosanthes seed for watershed programs in Karnataka and Andhra Pradesh was discontinued.

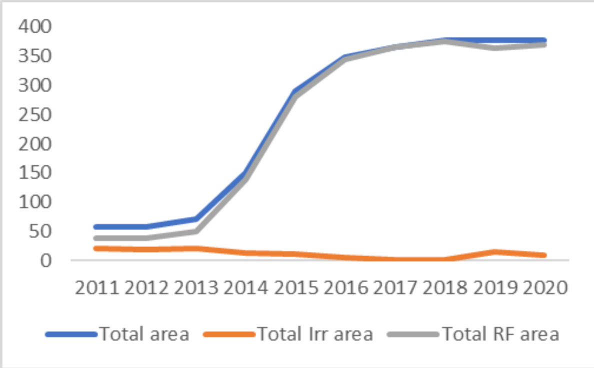

Figure 1 Average Irrigated and Rainfed area under Stylosanthes seed production 2011-2020

Percentage change in Stylosanthes seed production, yield and sale price from 2011 to 2020

Stylosanthes seed produced in 2011 was 36.25 metric tons which increased to 266.162 metric tons in 2020. However, seed production was greatest in 2017 (273.768 t) and in 2019 (274.079 t). There was a more than sixfold increase in area under Stylosanthes in the study area from 2011 to 2020. Correspondingly seed produced showed more than 7-fold increase. The increase in seed production was thus attributed to an increase in rainfed areas under Stylosanthes. There was a slight increase in seed yield (productivity) in different years with a minimum of 0.625 t/acre in 2011 to 0.727 t/acre in 2019. This minimal difference in seed yield might be due to favorable weather during flowering and seed set stage. Seed selling price in 2011 was USD 136.40/t. It increased to USD 308.40/t in 2018. The seed selling price, however, decreased in 2019 and 2020. Stylosanthes seed is traded by the respondents mainly through informal marketing channels. Middlemen who are in contact with different user agencies, mainly of public sector, get the orders. The price rise is directly related to the quantum of orders received by the middlemen. An increase in selling price thus might be attributed to the rise in demand for the seed. However, the selling price decreased in 2019 and 2020 due to a decrease in government orders for seeds as the increase in government expenditure to address the pandemic situation reducing allocation for agriculture and watershed projects. The average annual growth rate for seed production was 63.42 per cent, for seed yield 1.30 per cent and for selling price it was 1.16 per cent. Corresponding values for compound annual growth rates were 29.86 per cent (seed production), 1.09 per cent (seed yield) and 4.48 per cent (selling price). These findings indicate that changes in selling price was minimum in 10 years period while production showed good growth.

Decomposition analysis of Production Variability in Stylosanthes

Instability analysis on the area, production and productivity of Stylosanthes for a period of 10 years was carried out using Coppock's Instability Index (PII) as a measure for instability in Stylosanthes production. The results of the analysis indicated that about 52.90% of the total area was instable in the study area. Among the Stylosanthes, irrigated area was observed to be more instable compared to rainfed area. Production instability was observed to be 53.76 per cent. Seed yield and selling price were instable to the extent of 37.56 per cent and 55.1per cent. These findings confirm that the increase in Stylosanthes seed production was mainly because of an increase in area under Stylosanthes cultivation but not due to increase in yield level of the Stylosanthes.

Conclusion and Implications

The study highlights the significant growth in Stylosanthes seed production in Ananthapur district, driven by increased rainfed area cultivation due to its drought tolerance. However, irrigated areas declined due to preference for more lucrative crops. Market volatility and government demand fluctuations affect seed prices. Policy support and technological improvements are crucial for stable and enhanced production.

Impacts of grazing pressure and rangeland ecological potential on the degraded rangeland recovery of dry steppe

Dashbal, B[1]; Densambuu, B[2]

[1] Mongolian national federation of pasture user groups, Tokyo residence 6-606, building 26, 3rd khoroo, Bayanzurkh district, Ulaanbaatar, Mongolia

Key words: rangeland resilience, cover, grazing practice, livestock, carrying capacity

Abstract

The uncontrolled livestock population growth and increasing pressure on rangeland have led to a decline in rangeland productivity and shrinking of previously underused grazing areas. These rotational grazing practices have become increasingly difficult as heavy grazing accelerates the degradation of seasonal rangeland. Therefore, there is a critical need to identify community-supported and ecologically advantageous strategies for the recovery of degraded rangeland in the steppe zone, which is home to over 60 percent of the national herds. Efforts must be multidisciplinary, considering heterogeneous ecological sites to better understand the state of rangeland and to experiment with grazing regimes suited to the specific steppe climate and soils.

This study investigates the long-term (12 years) impacts of adjusted grazing pressure based on pre-study carrying capacity on the recovery of rangeland with varying degrees of degradation. The overall objective was to integrate grazing management practices informed by these findings into the rangeland management strategies of local herder organizations. Specific research goals included:

1. Determining how degraded rangeland could recover through grazing management tailored to its initial state and carrying capacity;
2. Understanding the interrelation of ecological site descriptions and the recovery class concept of degraded rangeland;
3. Determining the impact of grazing on the recovery of degraded rangeland in the steppe zone;
4. Assessing the effect of ecological potential on the restoration of degraded rangeland;
5. Developing a grazing model based on rangeland recovery and state change;
6. Piloting the optimal use of recovered rangeland at the herder community level.

Introduction

The decline in rangeland condition and productivity, which forms the foundation of livestock production and Mongolia's economic development, has been severe over the past 20 years. The steppe grasslands, which make up 66.12 percent of Mongolia's natural grasslands, are especially affected, with 30.8 percent categorized as dry steppes. Over 60 percent of the country's livestock graze in these areas. Degradation in this zone is expanding rapidly, underscoring the urgent need to develop and implement mechanisms for maintaining and recovering pastures at various degradation levels.

The national report on rangeland health of Mongolia (2015, 2018) noted that 80 percent of degraded pastures could recover naturally, emphasizing the importance of adjusting pasture use loads and regimes scientifically. Rangeland productivity, carrying capacity, and recovery potential vary depending on climate, geography, and vegetation. Therefore, research suggests aligning pasture use and recovery measures with the ecological capacity and degradation level of each site.

The continuous rise in livestock numbers has decreased the availability of underused pastures, limiting seasonal and rotational grazing possibilities. Consequently, it is critical to introduce practices that support the resilience and recovery of pasture ecosystems by balancing grazing pressure with environmental capacity. This study piloted the uniform use of degraded pastures in Undurshireet soum, Tuv aimag, from 2013 to 2022.

Methods

Field research focused on Steppe zone areas (n=4), representing typical pasture types. Data collection occurred between August 2009 and 2022. Enclosure and control plot pairs were established, with fenced plots measuring 25 m x 25 m. Three transects were set outside the enclosures and six inside. Samples were collected from 1 m^2 plots, with biomass and vegetative cover assessed and species diversity quantified using Shannon’s diversity index (SHDI). Data were analyzed using one-way ANOVA and Non-Metric Multidimensional Scaling (NMS) ordination.

Results

The study found that moderately degraded Stipa krylovii-Poa-Caragana steppe rangeland in deep sandy alluvial plains could support an additional 31 sheep units through controlled grazing. Long-term consistent grazing pressure over 12 years established sufficient forage resources for controlled herd management.

The ecological potential-based approach increased herder income by 10-15% through improvements in the livestock product value chain and certification based on set criteria. Moderately degraded pastures transformed into slightly degraded pastures within two years with balanced grazing loads.

Changes in total vegetation cover showed an increase to 97 percent under uniform use, while frequent use led to a decrease to 37 percent. Dominant plant species, such as Krylov's sedge, increased by 19-57 percent with uniform use but decreased by 7.5 percent with frequent use.

Discussion

The recovery of degraded grasslands in the steppe region is heavily influenced by annual rainfall and degradation levels. Studies indicate that once a threshold is exceeded, natural recovery within five years becomes unlikely. Recovery also depends on the dominant species' grazing tolerance and the balance between above-ground and underground biomass. Effective recovery requires methodologies that assess both visible and subsurface transformations.

Acknowledgements

We extend gratitude to Doctor of Agricultural Sciences Densambuu Bulgamaa and scientific advisor Batjargal Erdenebaatar for their guidance and support. Special thanks to the Swiss Development Agency's Green Gold Animal Health Project and Brandon Bestelmeyer for their collaboration in research methodology and article preparation. Finally, heartfelt thanks to our families for their support during this decade-long research effort.

Advocacy instrument to voice pastoralism: experiences and lessons learned from Ethiopia

Getahun, T[1]; Hussien, AA[2]; Tolossa, D[3]; Desta,SD[4]

[1]Pastoralist Forum Ethiopia, Addis Ababa University, tezerag@yahoo.co.uk (contact person); [2]Pastoralist Forum Ethiopia, abdidheere04@yahoo.com; [3]College of Development Studies, Addis Ababa University, degefa.tolossa@aau.edu.et; [4]FDRE Ministry of Peace (MoP), shanko_d@yahoo.com

Key words: Pastoralist Day, IGAD, Lobbying, Partnership, Networking

Introduction

In Ethiopia, pastoralists are over 14 million citizens (NDRMC 2018:2). They live in 182 Woredas[1] (23% of the total) across seven Regional States and Dire Dawa City (MoFPDA 2016; USAID 2018; NDRMC 2018). Pastoralists inhabit the country's lowlands, which are 60% of its land (IGAD 2017; MoFPDA 2018; DFID 2018). Almost all the pastoral inhabitants are considered rangelands. The pastoral population is diverse in ethnicity and social structure. 90% belong to the Afar, Oromo, and Somali groups. Most of these groups are in the country's peripheries. They have similar ancestry to those in the bordering countries. IGAD (2020:9) estimated the value of pastoral livestock at ETB 256.0 billion ($US 8.5 billion) in 2019. This includes cattle, camels, goats, and sheep. Pastoralists have faced marginalization and exclusion from decision-making. This is despite the benefits of their livestock-based livelihoods.

This paper

This paper aims to share lessons from advocating for pastoralism. We sought to improve the voice of pastoralists in Ethiopia's policy-making. We did this through a specific activity: the Ethiopian Pastoralist Day (EPD). Over the years, EPD's partners have developed the paper by reflecting on their work. The questions are: How much has the EPD helped mobilize pastoralists? Has it let them share experiences with each other and others? How much has EPD raised the profile of, and concern for, pastoralists? Has it created a supportive policy for their development at all levels? local, regional, and national? What have been the key successes and challenges of EPD? What did we learn from the lessons? This includes those for other pastoral communities outside Ethiopia. It also includes organizations that want to help them. The paper has been developed through a self- and peer-reflective process by individuals and partners who have been involved in the development of EPD since 1999.

The Birth and Development of Ethiopian Pastoralist Day

In 1996, elders and leaders from the Somali and Oromo groups in Ethiopia, along with the local NGO PCAE, organized a conference. They aimed to discuss the situation of pastoralists, marginalized and excluded for ages. They called for inclusive development, highlighting their unique pastoral system. That was the birth of the

[1]In Ethiopian Woreda administration equivalent to district

Ethiopian Pastoralist Day (EPD) in 1999 and its later development. Since the first celebration on 25th Jan 1999, EPD has been celebrated nineteen times. EPD is an *integrative* advocacy instrument. It is a unique event and process.

EPD brings together almost all pastoral actors in Ethiopia for a common cause. The Day is marked in the presence of pastoralists, policymakers, and Ethiopian dignitaries. EPD seeks to sway policymakers, the media, and development actors to change their policies and practices. PCAE and pastoral representatives organized the first three EPDs (1999-2001). They aimed to recognize pastoralism as a way of life and a viable production system. Ethiopia's pastoral groups are diverse in identity, location, and problems.

As a result, PFE has taken the role of spearheading EPD at the national level. Government and PFE collaborated on EPD from 2008 to 2022's 18th edition. The 19th EPD (25th Jan 2024) celebrated in Eastern Africa level, in partnership with IGAD, in Addis Ababa, Ethiopia. We believe that the collaboration among these institutions makes EPD a powerful advocacy tool.

Key Successes and Challenges of EPD

EPD mobilized pastoralists and created a platform for sharing experiences. It has been celebrated in rotation at national and Ethiopian regional levels. The pastoralists share customs, environments, and development from each avenue. Pastoralists from different areas can discuss their issues and present to the government. The local word, Zelan, means "wanderers and lawless." It's a derogatory term. It's been fading away. They are now called *Arbetoader* (pastoralists). It was in 2008 (eight EPD) that the Government of FDRE recognized EPD as a National Day. This is a milestone in the advocacy and lobbying work of the PFE and partners.

EPD raised awareness of pastoralists and improved policies. At each EPD, pastoralists made resolutions. They called for recognition of their unique livelihoods. They also requested pastoral-focused institutions. The EPD influenced the Federal Parliament's establishment of the PASC. In 2021, the Ministry of Irrigation and Lowland (MILL) was established. Various regional pastoral governments have also been formed. Later national plans (e.g. poverty reduction or growth-transformation papers) included pastoralism. They also increased pro-poor services (health, education, water) threefold. So far, we see two challenges. First, EPD is not well-institutionalized. It lacks a clear monitoring and evaluation system. Second, EPD is slow to move to the regional and continental levels. This would benefit pastoralists in neighboring countries by creating opportunities.

Fig. 1. 19th EPD and East Africa Pastoralist Expo celebration in the presence of high-level government delegates in Ethiopia, pastoralists and guests

Lessons Learned for Other Countries

EPD's multi-pillar approach has opened new opportunities to influence policy. EPD has united disadvantaged groups by working with various actors. These include national and local governments, elders, representatives of marginalized communities, Civil Societies and media. They now have a common voice that supports pastoralism.

Conclusions and Implications

The EPD has proved a challenging but innovative way to raise the voice of pastoralists. It aims to boost the profile and investment in pastoralism. It is a way of life, a productive livelihood, and a land use system. EPD has changed social development. It included a pastoral agenda in policy work.

The FDRE Government has recognized EPD as a "national day." High-level officials, including the Prime Minister of Ethiopia, attend the celebration. However, some compromises and trade-offs have had to be made along the way in order to address some of the challenges faced. Though the situation for pastoralists has improved, much remains to be done. We must fully recognize and support their potential and livelihoods. The continental and regional African bodies would use EPD's lessons to promote integration and peace.

Increasing education and awareness on grassland ecosystems through the development of curriculum

Gordon, KL[1,3]; Rokosh, SM[2,3], Gardner, WC [1]

[1] Thompson Rivers University, Kamloops, BC, Canada; [2] Kamloops-Thompson School District 73 BC, Kamloops, BC, Canada; [3] BC Conservation Foundation, Kamloops, BC, Canada.

Key words: education; outdoor learning; curriculum development; temperate grasslands

Abstract

Temperate grasslands are among the most endangered ecosystems globally, a situation mirrored in Canada, where significant portions have been lost. In British Columbia (BC), temperate grasslands cover less than 1% of the province but are crucial for over 30% of its species at risk. Despite their importance, there is limited awareness and education about grassland ecosystems and their services. Many teachers hesitate to focus on grasslands due to a lack of understanding and an absence of developed lesson plans that align with curriculum requirements. A project aimed at developing and piloting an elementary school curriculum on BC's temperate grasslands was therefore undertaken. The goal was to educate students and teachers about this endangered ecosystem in their region, foster local involvement, and gather support for grassland stewardship. The interdisciplinary curriculum meets the learning outcomes required for BC's public elementary schools, including embedding First Peoples Principles of Learning. Each of the three units contains ten independent lessons, which will all be available online. This will allow teachers to use the entire curriculum or select individual lessons to study. Portions of the first unit, "Grasslands: Grounding in Place," were piloted in grade 4 classes in fall 2023, complemented by field trips with elementary students. Feedback was positive, leading to a full-scale pilot in fall 2024. An outcome of this initiative was a partnership with the creators of BC Tomorrow, a free simulation tool that enables students to explore resource use and consider social, economic, and environmental factors. BC Tomorrow now includes a learning module about grassland ecosystems, which is available nationwide. This work is vital for raising awareness about grassland ecosystems and promoting further stewardship. Educating students and teachers about the significance and conservation of temperate grasslands will help ensure that these critical habitats are preserved for future generations.

Introduction

British Columbia's temperate grasslands are endangered and cover less than 1% of the province's land area, yet they provide many ecological goods and services (Iverson 2004). These include diverse habitats for plants and wildlife, flora for pollinators, nutrient cycling, carbon sequestration, and opportunities for recreation and outdoor education (Iverson 2004, Gayton 2013). However, there is a lack of awareness of the importance and function of grassland ecosystems in BC, especially within the public school system.

Many educators are hesitant to focus on grasslands due to a lack of understanding and the absence of developed lesson plans that align with curriculum requirements. Furthermore, recent updates to the BC Curriculum (PoBC 2024) have prioritized flexible learning environments and inquiry-based learning. The BC curriculum redesign has therefore heightened educators' existing interests in experiential and place-based learning and their desire to take students outdoors (Asfeldt 2021, Gruno and Gibbons 2022). Additionally, this curriculum redesign may allow for increased collaboration between teachers and community groups or organizations whose priorities include education.

Flexible learning environments may also include the use of virtual, interactive resources. BC Tomorrow is a non-profit society that has developed a peer-reviewed simulation tool, which allows students to explore the impact of land uses on environmental, social, and economic variables (BCTS 2024). Their mission is to "help students and teachers explore sustainability when considering land use decisions in BC," (BCTS 2024). In addition to the simulator, there are opportunities to extend student learning with 'quests' that encourage students to explore the outdoors and create and upload personal field observations. The BC Tomorrow simulator features watersheds and a variety of ecosystem types, however, it lacks a grassland learning module.

To acknowledge the demand for outdoor education resources and address resource gaps, a collaborative pilot project aimed to develop and deliver an elementary school curriculum about BC's temperate grasslands. The objectives of the pilot project were to create an interdisciplinary elementary-level curriculum and complementary outdoor learning opportunities that aligned with BC's curriculum and embedded First Peoples Learning Principles throughout. A secondary objective was to collaborate with BC Tomorrow to develop a grassland module to complement the elementary-level curriculum lessons.

Methods

The curriculum was developed as part of an arts-based Master's in Environmental Education and Communications thesis (Rokosh 2024). A literature review of existing grassland-themed education resources was initially conducted by undergraduate students at Thompson Rivers University in Kamloops, BC. Semi-structured interviews were then conducted with local environmental non-profit organizations to address grasslands specific to the Thompson Okanagan. This literature review, coupled with the overview of the BC curriculum, helped identify gaps that could be addressed in the interdisciplinary grassland-themed curriculum.

Classroom planning involved preparing an 'Introduction to Grasslands' presentation and various interactive grassland-themed activities. First, a sensory 'smell box' (Annnenberg Learner 2020) contained fresh sprigs of big sagebrush (*Artemesia tridentata*), a shrub native to BC's grasslands, for students to experience. Next, we modified an outdoor colour scavenger hunt (Staten 2024) by completing the activity indoors and asking students to relate the colours to their local grassland area. Lastly, students were provided with various pressed grassland plant samples to showcase growth forms and colours, then asked to identify one similarity and two differences. Following the station-based activities, students completed a 'Know, Wonder, Learn' (KWL) activity (TLA 2024).

Field trip reconnaissance took place in September 2023 and locations were selected based on bus accessibility, trail difficulty, the grassland plant community, and outhouse access. Juniper Park, located in Kamloops, BC is a community park with a playground and a network of marked grassland trails and was selected for field trips in 2023. The 2023 field activities included a grassland-themed bingo game, a colour-chip scavenger hunt, and a nature journalling session (John Muir Laws 2017). In 2024, field trips were in Lac du Bois Grasslands Protected Area (Lac du Bois). Lac du Bois is located north of the Kamloops city center and is a Provincial Protected Area that captures 15,712 hectares of grassland, forest, and riparian ecosystems (BC Parks 2023). Lac du Bois field activities included exploring land uses, a 'create a creature' journalling exercise (ASTCSWS 2024), and a grassland eye-spy game.

Results

Unit 1 of the "Explore and Understand the Grasslands!" curriculum is titled "Grounding in Place" and includes ten interdisciplinary lessons (Table 1). Each lesson captures at least two learning objectives that align with BC curriculum and has First Peoples Learning Principles embedded throughout (Table 1).

In 2023 the curriculum was piloted in four classrooms at South Sahali Elementary School on September 29th and October 11th. Complimentary follow-up field trips were held on October 18-19th where 45 grade 3-5 students participated each day. In 2024, Marion Schilling Elementary School and South Sahali Elementary school grades 3-5 participated in the in-classroom presentation and field trip sessions to Lac du Bois. Four classrooms were visited on October 4, 2024, with field sessions occurring on October 11th and 18th.

Table 1. The lesson plan and learning objectives for the "Explore and Understand the Grasslands!" elementary-level curriculum Unit 1 - Grounding in Place.

Lesson #	Lesson Title	Learning Objectives
Lesson 1	What is a biome?	1) Students will identify the seven major biomes of the world. 2) Students start to explore interconnectedness within biomes i.e., food webs and cycles)
Lesson 2	An Introduction to Grasslands	1) Students will learn the location and broad features of grasslands both globally and locally 2) Students will reflect on what they wondered and what they now know
Lesson 3	Grasslands and Tk'emlúps Place Names	1) Students will listen to stories of the area to gain a deeper understanding of the history and feeling of the place. 2) Students will practice expressing a story (either their favorite story, or a version of a place-name creation story)
Lesson 4	Introduction to Journaling	1) Students will start to create their own field journals and gain understanding of the many purposes of journals 2) Students will make observations, ask questions, make connections, and learn about something that piques their interest.
Lesson 5	Observing our Landscapes and Outdoor "Mapping"	1) Students will spend time outside with their journals and record observations of their local landscapes 2) Students will create a map of their surroundings 3) Students will learn/explore elements of maps (orienteering, scale, legends, etc.)
Lesson 6	Indoor Mapping Activity	1) Students will see how their local area has changed over time and what it could look like when they get older. 2) Students see that human activities on the land impact water.
Lesson 7	Watersheds Part 1: What are those?	1) Students locate their watershed on a map using satellite imagery. 2) Students identify key places or significant features that exist in their watershed.
Lesson 8	Watersheds Part 2: What will this watershed look like in the future?	1) Students see how their local area has changed over time and what it could look like when they get older. 2) Students see that human activities on the land impact water.
Lesson 9	Introduction to Adaptations, Relationships and Interconnectedness	1) Students explore how grassland soils, plants, animals and climate/weather are connected. 2) Students observe how grassland plants and animals are adapted to their
Lesson 10	Field Trip to the Grasslands	1) Enhance students' understanding of grassland ecosystems by exploring them in person 2) Students learn and practice how to be a responsible land user while exploring the grasslands or any outdoor space

The KWL activity demonstrated that some students 'knew' that grasslands are hot and dry and knew about grassland plants (i.e., drawings of flowers, grasses, with few trees) and the variety of animals that live in grasslands. Other students 'wondered' what animals and plants live in grasslands and how living things survive and grow there. Following the grassland in-class presentation, students 'learned' that grasslands are endangered, how plants and animals adapt to living in hot and dry environments, and how we can help take care of our grasslands through stewardship efforts (i.e., walking on trails and cleaning up garbage).

The BC Tomorrow Society collaboration resulted in a 7.38-minute-long video that details the role of grasslands in supporting biodiversity and sustaining local communities that will be used to complement the grassland curriculum lesson plans.

Discussion [Conclusions/Implications]

The objective of this pilot project was to develop an elementary-level curriculum to help educate students and teachers about grasslands in their region. A secondary objective was to collaborate with BC Tomorrow to develop grassland-focused learning modules to supplement the curriculum. This project highlights the importance of providing outdoor learning opportunities for elementary-level students. Students were highly engaged in the grassland curriculum and clearly expressed an admiration of their surroundings when exploring in Juniper Park and Lac du Bois. Studies have found that outdoor learning can increase a students' appreciation for nature, amongst other benefits such as improved self-confidence, physical and social skill development, and enhanced creativity (Boileau and Dabaja 2020). We also observed that grade 3-5 students are resilient to variable weather and maintain an overall positive attitude while exploring and learning in the outdoors.

The next steps in this project are to develop a diverse steering committee composed of educators and First Nations community representatives to help review and provide feedback on the curriculum. Furthermore, follow-up classroom visits will occur that will involve the BC Tomorrow grassland video and learning modules using the virtual simulator. Lastly, educators involved in the project will also continue expanding dissemination of curriculum through conference opportunities.

Acknowledgements

This project would not have been possible without support from the Stober Foundation, the Grasslands Conservation Council of BC, BC Conservation Foundation, BC Parks, and the Habitat Conservation Trust Fund.

Educating rangeland ecology and management professionals in the 21st century

Ingham, CS[1]

[1]Animal & Rangeland Sciences, Oregon State University, Corvallis, Oregon 97331, United States of America

Key words: rangeland sciences; online education; experiential learning; early career professional development and networking; Bachelor of Science

Abstract

Essential knowledge and skills required of rangeland managers have traditionally been taught on land-based campuses with access to field sites. However, as the demand for online education has grown and enrollment in traditional rangeland sciences programs has declined, Oregon State University (OSU) has adapted by offering an online program (Ecampus) and hybrids of on-campus and online programs to enhance enrollment and maximize the availability of faculty to students in all modalities. The Animal and Rangeland Sciences Department at OSU currently educates ten percent of all undergraduates earning a rangeland sciences, or related degree, as accredited by the Society for Range Management (SRM).

A description of the degree, the required coursework and quality assurance through accreditation are detailed. Student advising practices and the availability of extracurricular activities, including participation in SRM are included. Despite the OSU Rangeland Sciences program's design to capture an ever-increasing number of students who seek online education, low enrollment and lengthy periods for degree completion are viewed as impediments to maintenance of the multi-campus program.

Introduction

The Rangeland Sciences program in the Department of Animal and Rangeland Sciences at Oregon State University (OSU) educates students by offering a Bachelor of Science degree as well as educating non-degree-seeking, post-baccalaureate, students. This model of educating traditional undergraduates and working professionals provides a diverse learning environment for all learners. Professionals working on rangelands gain knowledge of ecological principles while their classmates gain from the professional experiences of their classmates seeking continuing education for career advancement. Degree-seeking students can earn the Rangeland Sciences degree via three different pathways which include: 1) coursework on the Corvallis campus, 2) coursework on the La Grande campus or 3) coursework via the online offering, Ecampus. Students can attend via any combination of these three pathways. Many students are post-baccalaureate who are fulfilling requirements needed to advance in their careers as per the Office of Personnel Management (OPM) requirements for positions with the US Federal government.

To enrich the learning options for all students, faculty have developed 'field hybrid' courses in which students from any of the three pathways can enroll. The current trend is increased Ecampus enrollment with growth of 4%, year-over-year, to 11,430 in the fall of 2023 (Nealon, 2023). Concurrently, there has been a decline in enrollment on the Corvallis and La Grande campuses.

Educational Program (Methods)

Degree Description

Rangeland Sciences at OSU is an undergraduate degree which focuses on the ecology and management of rangelands across a variety of arid and semi-arid ecosystems including shrublands and grasslands (Rangeland Sciences Undergraduate Major 2024). This program uses a multi-disciplinary approach to provide advanced scientific knowledge of ecological processes and social drivers influencing rangeland ecosystems around the globe. Students gain the skills and knowledge needed to understand and effectively manage rangelands for improved productivity and enhanced ecosystem resilience. The goal is that graduates of the program will be able to integrate contemporary rangeland ecology and management principles into a systems-based decision-making framework that promotes ecological resilience, sustainable societies, and thriving economies in rangeland systems.

Required Coursework

To earn the Bachelor of Science, students must complete eight upper division courses within the Animal and Rangeland Sciences Department as well as the usual mathematics, statistics, life sciences, chemistry, writing and humanities electives. Departmental faculty members teach rangeland ecology principles, wildland plant identification, ecology of grasslands, ecology of shrublands, rangeland ecohydrology, vegetation monitoring and analysis, restoration and management, rangeland-animal relations and rangeland management planning principles and processes (Rangeland Sciences Undergraduate Major 2024). Electives in wildlife habitat analysis, riparian ecohydrology and management and pastoral systems of the world are also offered. Related coursework in Botany, Soil Science and Fisheries and Wildlife Conservation are offered by those Departments, also in the College of Agricultural Sciences.

Teaching Modalities

All courses are offered on-campus and via Ecampus with the same student learning objectives for all sections. This requires innovation on the part of faculty as the asynchronous online learning environment changes the nature and timing of faculty-student and student-student interactions. The usual dialog in on-campus courses is conducted in a modified manner via Discussion boards within the learning management system (LMS). Questions within Ecampus Discussion require application of course content as well as interaction with peers and faculty. Recorded lectures, with captioning, are part of every weekly Module in the Ecampus sections of the courses. Incorporation of research faculty work and research outcomes are shared across the courses with guest lectures and accompanying required reading. When courses are developed, and updated through a 're-development' process, specialists in online education work with the Rangeland Science educators to ensure up-to-date resources are used. Most courses are taught by one or two individuals across the three campuses.

Maintaining Quality

The Rangeland Sciences degree is aligned with the US Office of Personnel Management (OPM) standards which allows graduates to begin careers with the US Federal government in various agencies including the US Department of Agriculture and the US Department of the Interior. Graduates are also sought by State land management agencies, private land trusts and private landowners such as livestock producers.

The undergraduate degree program at OSU is accredited by the Society for Rangeland Management (SRM) with the most recent review in 2023. The seven SRM Accreditation Standards for University Accreditation include criteria for the education of the faculty, role of faculty within the university, degree name, depth and breadth of the curriculum, advising of students, extracurricular opportunities for students, continuing professional development of the faculty, self-assessment of program effectiveness and university support for the program. The SRM criteria-based system is valued by educators as well as rangeland ecologists and managers. This and other endorsements of university programs are highly valued by university administrators. OSU (2024) is a member institution of the Northwest Commission of Colleges and Universities (NWCCU) and shares this information with the public via web pages and reports. This is a critical component of maintaining public trust.

To meet the requirements for accreditation of OSU by the NWCCU, a set of five programmatic learning outcomes was established by the teaching faculty. These are aligned with SRM standards. Student performance data are collected from all sections of courses in which the programmatic learning outcomes are taught. Faculty review performance on an annual basis with guidance from the Assessment Lead who is a peer in the academic unit. Comparisons across campuses and across time are used to revise teaching and assessment methods.

Orientation and Advising

All students who enroll as freshmen at OSU are required to attend a START new student orientation session whether on campus or in a virtual session (Office of Student Orientation 2024). These sessions introduce students to academic, financial and social resources. Family members can also attend specialized sessions which include how to support the student and family transitions when sending a student to college.

Each student meets with an assigned Advisor to review course selection for the upcoming academic term. Extracurricular activities, including summer internships or employment are also discussed. These regular interactions ensure that students enroll in courses for which they are prepared and those which are most suited to the degree. Post-baccalaureate students have diverse educational goals and so advising them is complex as it requires consideration of past collegiate level coursework and work-life balance concerns.

Field-based Learning and Faculty Innovation

Four of the eight required courses included multi-day field trips to locations in northeast, central and southeast Oregon, prior to 2011 when two academic units were merged. Although field trips are still required in some on-campus courses, budgetary pressures and the transition to include the Ecampus program have been challenging for faculty. Concurrently with Ecampus course development, on-campus enrollment declined and over the past decade the number of courses with required field trips has declined as well.

To address the need for experiential learning, Ecampus and many on-campus sections now include activities that require students to explore rangeland ecology principles, no matter where the student lives. These assignments require students to select a field site to explore. Careful, step-by-step instructions must be followed and students document their work with photos, descriptions and video clips of their efforts, observations and conclusions. Complete work is uploaded into the online learning management system for view by faculty and peers. Peer evaluation is incorporated where appropriate. In this way, a student can see a location not available to them and receive feedback on what their classmates observe. Students in urban areas are provided coaching on how to select a park or natural space that is most suitable. In the grassland ecology course, a student living in Las Vegas, Nevada was directed to conduct the grassland ecology activity in the riparian zone of a local river. Site characteristics had to meet the requirements of the assignment. While the student was not exploring an established grassland, the site provided a suitable stand-in for the examination of deeply-rooted perennial grasses and the other components of the assignment.

Another innovation to address the need for hands-on learning is the 'field hybrid'. Faculty based at the OSU Eastern Oregon Agriculture and Natural Resources Program office a 'field hybrid' version of the vegetation measurement and analysis course (see **Required Coursework** above) in which students spend a week at the Starkey Experimental Forest and Range and the Zumwalt Prairie in Northeast Oregon. This intensive week-long session is open to students enrolled at the Corvallis, La Grande or via Ecampus. Following the field week, students complete course content in a merged Ecampus section. A Corvallis-campus based faculty member has also developed a section of rangeland-animal relations course as a field hybrid which includes tours of cattle ranches, Bureau of Land Management Wild Horse Corrals and interaction with rangeland conservationists in Oregon's sagebrush steppe.

Results

Degree Completion

As rangeland sciences programs face declining enrollment at many educational institutions, faculty have adopted methods of program delivery to suit the twenty first century learner. Several trends are evident. Many students require more than the historic norm of four years to complete a degree. Others seeking professional development related to their current employment enroll in courses on a sporadic basis. This might be one course per academic year or a few courses over three-four years. Students seeking a degree in this manner are not counted in the traditional manner universities use to document student success, i.e., degree completion and years required for completion. Thus the benefits provided by the Rangeland Sciences program go unrecognized because they do not meet traditional metrics of success.

While hundreds of students have earned degrees on the Corvallis and La Grande campuses, only twenty students have earned a Bachelor of Science in Rangeland Sciences via Ecampus since its inception (Duerfeldt, 2024). All other Ecampus enrollees are post-baccalaureate or are on-campus students seeking particular faculty or flexibility in their academic schedules.

Employment of Graduates and Professional Networking

A formal record of graduate employment following the awarding of a Bachelor of Science in Rangeland Sciences (Rangeland Ecology and Management prior to 2011) is not available. However, current and retired faculty members interact with graduates and thus anecdotal information is available. Students are employed by the US Forest Service, US Bureau of Land Management, State land management agencies, land trusts and on private ranches.

Students benefit from faculty introducing them to their professional networks, particularly within the Society for Range Management. These relationships are reinforced at annual International SRM meetings such as the February 2025 meeting in Spokane, Washington. In some instances, due to Ecampus enrollment, the first face-to-face interaction between students and faculty occurs at a SRM meeting.

Discussion

Declining enrollment in the on-campus programs has challenged university administrators and teaching faculty for at least 15 years. Numerous factors contribute to this trend including faculty attrition, lack of awareness and promotion of the on-campus degree programs and competition due to other similar degree programs such as Environmental Sciences in the College of Earth, Oceanic and Atmospheric Sciences and the Natural Resources degree in the College of Forestry. Students in other degree programs take advantage of the rangeland sciences coursework to meet the breadth requirements of their degrees yet do not complete the Rangeland Sciences degree. Faculty in the Rangeland Sciences degree program report anecdotally that some students would have chosen to earn Rangeland Sciences degrees had they been aware of the opportunity earlier in their undergraduate educational career.

It is anticipated that the Ecampus program will remain a strength whether those enrolled seek a Bachelor of Science degree or enroll as post-baccalaureate students completing continuing education as part of their professional development. Because the Rangeland Sciences program provides essential content for other natural resources-related degrees at OSU, the faculty in this academic group will continue to provide relevant applied ecology education for those students.

Conclusion & Implications

Continuation of the Bachelor of Science in Rangeland Sciences degree at OSU will demand innovation, increased enrollment and collaboration across departments and with other universities. Increased use of simulations could enrich online course offerings and expansion of the field hybrid course offerings would enhance undergraduate learning with hands-on coursework.

Despite the prominent level of faculty collaboration with other universities, land management organizations and the ranching community, increased student enrollment and increased degree completion are the factors that will make the Rangeland Sciences degree program valuable to administrators who must justify its costs.

Sustainability and resilience of the Mongolian indigenous rangeland

Khaidav, D[1]; Yundendorj, Ts[2]; Sodnom, M[3].

[1, 2] Development Interlink NGO, Mongolia; [3] World Herder's Association, Mongolia.

Key words: Mongolia's rangeland culture, adaptability.

Abstract
Mongolia's indigenous civilization relies on the rangeland system for grazing the livestock. Three main risks to traditional animal husbandry exist including pasture degradation, unnatural livestock deaths, and negative impacts of new civilization unfavourable to animal husbandry. Mongolia's traditional animal husbandry has sustained through managing these three risks, and animal husbandry production has continued to grow. The second risk has been mitigated traditionally by pastoralists through generations. Accordingly, herds of adult animals can recover quickly as environmental conditions improve. The third risk is successfully mitigated by the modern animal husbandry sector. This is evidenced by the fact that Mongolia's rangeland culture is still considered sustainable, adaptive, and resilient despite intensified agricultural, infrastructure, and mining developments, as well as urbanization during the past 100 years.

Introduction
Mongolia's traditional pastoral culture has evolved by adapting to the favorable and unfavorable conditions of nature. Mongolia's gross livestock output has continuously been on the rise since the year 2000. In this paper, we explore how Mongolia's traditional pastoral culture has adapted to and stabilized in response to the challenges and opportunities presented by modern urbanization and technological advancements. On the one hand, Mongolia's livestock behave like wildlife, independently foraging for grass and grazing selectively; on the other hand, it represents society and culture as it is an integral part of the life of pastoralists. Thus, it is entirely possible to view Mongolia's traditional pastoralist civilization as a model of harmonious coexistence between nature and society.

The sustainability of traditional animal husbandry is primarily due to its spread across more than 1.5 million square kilometers and its ability to maintain the vastness and sufficiency of its pastureland. Livestock herding follows four main procedures, each carefully adapted to the specific conditions of the four seasons. Each season involves a distinct set of activities, while preparations for the next season begin during the current one. The effectiveness of the preparations will determine how successfully the new season is managed. In this way of following a one-year cycle of four seasons, traditional animal husbandry production differs markedly from the production of other commodities and goods. The animal husbandry industry is complex and encompasses a wide range of activities, including livestock herding, herd management, pasture selection and utilization, seasonal livestock migration (plus otor), winter camp facilities management, livestock birthing and raising, feeding, and fat deposition, reserving fat, overwintering, watering, salt supplementation, hay and fodder management, sheering, milking, etc. Knowledge and expertise in these complex operations are essential to the success and sustainability of the pastoralist business.

Methods

Using livestock statistics from Mongolia (National Statistics Office, 2024), the data were processed using simple mathematical calculations, and key indicators were calculated for presentation in tables and graphs, which were subsequently interpreted to draw conclusions. Approximately, 10 tables and graphs are included in this study and will be featured in the poster presentation.

Results

The number of herder households in Mongolia fluctuates by approximately 12%, influenced by natural conditions, with an average of 170,000 households over the past 32 years. 'Herder Households-I' has grown to 188,000, while 'Herder Households-II' has declined and stabilized at 60,000. Livestock distribution varies across soums, with an average of 735 livestock-owning households per soum. Mongolian pastoralist communities maintain a strong cooperative culture, supported by modern communication. Traditional livestock management practices, including breeding control and risk management, have contributed to stable livestock survival rates, even during environmental challenges such as dzuds and droughts. Over the past 51 years, the average annual livestock mortality rate has remained below 8%, highlighting the resilience of Mongolian pastoralism.

Discussions

In the age of globalization, where the cultures of many countries are being introduced to Mongolia, it may seem that the country's traditional pastoral animal husbandry is at risk of being overshadowed and potentially destroyed due to conflicts with urbanization, crop farming, transportation, and mining development. On the contrary, the gross livestock output is constantly growing. So, where does the secret behind the stability, adaptability, and regenerative capacity lie? The results of our research several potential answers, outlined below.

1. Interest in livestock herding remains strong among families, and the number of herder households tends to fluctuate by approximately 12%, depending on favorable or unfavorable natural conditions. Based on data from the past 32 years, the average number of herder households is 170,000, with fluctuations occurring approximately every 7 years. Furthermore, during one-quarter of the 32 years, the number of herder households declined, while it increased during the remaining three-quarters of the same period. The number of herder households increased by up to 21,000 during three years of favorable climate conditions, while it decreased by nearly 26,000 over three years of unfavorable weather.

The number of 'Herder Households-I' (households primarily engaged in livestock farming) increased by 45,000 compared to 1992, stabilizing at 188,000. In 2001 and 2010, marked by severe drought and dzud, the number of herder households declined, followed by a subsequent resurgence. On the other hand, the number of 'Herder Households – II' (households that participate in the official livestock census and rely on a combination of livestock and non-livestock income sources) declined for approximately 10 years, from 158,000 in 1992, when livestock was privatized, to 60,000 over the past 20 years, where it has since stabilized. The number of households participating in the livestock census appears to be less affected by dzuds, likely because they raise fewer animals with adequate hay and fodder reserves or engage in more intensified farming practices. Further study is needed to explore this in more detail.

2. Households with livestock are distributed throughout Mongolia, with 200-400 households in 34 soums, 450-950 households in 224 soums, and 1,000-2,000 households in 72 soums. The average number of livestock-owning households per soum is 735. The distance between herder families varies, depending on factors such as the four-season cycle of the year, precipitation, pasture yield, and the need for cooperation and collaboration. During winter, this distance ranges from 5 to 20 km, with a family possibly moving between two to three winter camps to access pasture.

3. The moves of livestock and herder households, coupled with the communal use of pastureland, have fostered the development of a unique pastoral community culture. The pastoralist community has a concentric structure,

with herder households sharing a common pasture at its core and allies from soum and provincial centers forming the outer layers. IIn the outermost circle are relatives and friends living in the capital city of Ulaanbaatar, other provinces and soums, and even abroad. A herder family may be familiar with other families within a 100 - 200 km radius. This layered structure of pastoralist communities is rooted in a traditional culture where the brotherhood among pastoralists is strong, and there is a sincere commitment to helping one another within the shared pasture. In Ulaanbaatar and other provinces, the 'Nutag/Local Councils' are established at the intersection of nomadic and settled cultures uniting Mongolians with a pastoralist way of thinking. The modern-day layered structure of pastoralist communities enables herders to access a wide range of information, goods, and services without the limitations of space and time by using information technology.

4. Livestock breeding, or the suspension of breeding, is integral knowledge embedded in Mongolian traditional herding practices. Breeding management is carried out with consideration of summer precipitation, winter snow, and cold forecasts, the availability of labor within the herder family, and the livestock's condition, including fat reserves and strength. Traditionally, measures have been implemented to limit the number of breeding livestock, particularly during years of drought and dzud. Suspending the breeding of mother animals can be a strategic measure to reduce fat loss for the livestock during harsh winters and to lessen the workload associated with birthing and rearing in the spring. During 2019-2021 with the COVID-19 pandemic, Mongolian herders suspended livestock breeding, increasing the number of non-breeding mother animals by 6-7 times compared to the average in previous years. This measure significantly eased the burden on herders, allowing the animal husbandry sector to remain stable throughout the pandemic and even achieve overall production growth. In contrast to restrictions on production processes in some countries, where workers protested to express their desire to work, Mongolian herders continued their usual herding activities.

5. Statistics from the past 53 years show that practices related to the delivery of animal babies and newborn care have been passed down through generations and have remained consistent. Livestock rearing refers to the proportion of animals successfully raised out of every 100 born. Except for two major drought and dzud in 2001 and 2010, respectively, livestock rearing has remained stable over the past 53 years. Even during the COVID-19 pandemic (2018-2022), the rearing rate remained stable on average, without any decline, which is a testament to the effectiveness and resilience of Mongolian traditional livestock-rearing methods.

6. The risk management techniques of Mongolians have a centuries-old tradition, as key risks to animal husbandry, such as droughts and dzuds, have long shadowed pastoralists since the earliest days of herding. This can be likened to the experience of countries with cultures of resilience in overcoming natural disasters, such as hurricanes, earthquakes, and tsunamis. Drought risk management involves a broad range of activities, including weather forecasting, livestock migration (otor), pasture management and scheduling, hay and fodder preparation, setting breeding caps, culling animals, and preparing infrastructure such as fencing and water points, as well as salt supplies. Orkhon, Selenge, and Darkhan-Uul provinces are key areas for hay and crop production, with numerous entities and cooperatives operating in fodder preparation, sale, and transportation. The degree of dzud disaster varies for the Gobi and Khangai regions. There have been occasional instances in the Khangai region where summer conditions were relatively favorable, and severe winter and spring conditions, including sudden snowfall and dzud, have led to significant livestock losses. In contrast to the Khangai provinces, the Gobi region experiences lower livestock loss, suggesting that summer conditions in the Gobi may enable better winter predictions, allowing drought-affected herders to prepare more effectively. The National Emergency Management Agency of Mongolia has experience taking swift action during droughts and dzuds to minimize livestock losses and support herders.

7. The primary goal of livestock grazing and herding in Mongolia is to ensure the survival of livestock through all four seasons without losses/mortality. Overwintering involves two key priorities: ensuring that animals gain sufficient fat and strength and minimizing animal mortality. Grazing is a fundamental aspect of Mongolian livestock management, as animals rely on pastureland to acquire the necessary nutrients for growth, fattening, and other outputs. As a result, herders pay significant attention to pasture selection and effective herding practices. Livestock that have access to high-quality pastures and receive proper herding care are more likely

to survive the winter and yield higher-quality products, such as wool, cashmere, and milk. A grazing animal roams freely in a pleasant natural environment, with access to fresh air, clean water, and new grass. This daily activity promotes the animal's health and supports its overall well-being. Among the many plant varieties that thrive in dry conditions, the best are consumed by livestock. The vast pastures are also home to numerous medicinal plants. Meat, milk, and dairy products from livestock fed with nutritious plants, and not stressed are true natural Mongolian products—high in quality, though produced in limited quantities. Improved animal well-being and higher outputs bring happiness to the herder.

Converting mobile pasture-based livestock to a settled farming system presents several challenges. Above all, pasture livestock have a very different temperament than the farmed animals. With an introduction to fenced pastures, they may experience physical changes and emotional stress due to their limited mobility.

The main goal of Mongolia’s traditional animal husbandry is to maintain or increase the livestock population. Accordingly, herders often focus more on the high survival rate of their livestock during the winter than on quantifying meat sales. Over the past 51 years, statistical data show that the average annual livestock mortality rate is less than 8%. Although herd sizes decrease during dzuds and droughts, they recover and grow again in cycles of favorable weather. This ability to reproduce and restore is inherent in traditional pasture livestock. It provides herders who have faced losses from droughts and dzuds with confidence in the future and the motivation to rebuild their herds.

Conclusion

Mongolia's traditional pastoral livestock system has demonstrated remarkable resilience, adaptability, and regenerative capacity despite pressures from urbanization, mining, and crop farming. The stability of the herding population, strong communal ties, and effective risk management strategies have allowed pastoralism to persist as a vital economic and cultural practice. Time-tested breeding management, disaster preparedness, and sustainable pasture use contribute to stable livestock production, even in the face of environmental challenges such as dzuds and droughts. These factors underscore the enduring viability of Mongolian pastoralism in the modern era.

Implications

The resilience of Mongolia’s pastoral system suggests that policies should continue to support traditional herding practices while integrating modern technology and sustainable resource management. Strengthening local herder networks, improving access to weather forecasting and fodder reserves, and preserving communal pasture use can further enhance adaptation to climate variability. Additionally, recognizing the economic and cultural value of pastoralism may encourage efforts to balance development with the preservation of Mongolia’s unique herding heritage. Further research is needed to explore how intensified farming practices and alternative income sources can complement traditional pastoral livelihoods.

Pastoralist at the crossroads: the struggle for land ownership and forceful relocation. A case of the Maasai pastoralists of Loliondo and Ngorongoro in Tanzania

Laizer, J[1,2,3]; Lekaitogo, J[1]; Masanja, J[1]: Nashipai, C[1]; Mushy, R[3]

Abstract

The interplay between land tenure and governance significantly impacts the stewardship of rangelands, affecting Indigenous peoples and pastoral communities. This paper explores the evolving dynamics of land rights, particularly in areas like Ngorongoro and Loliondo in Tanzania, where communities face challenges due to land appropriation under the guise of conservation and economic development. The study urges equitable governance and emphasizes recognizing land rights and promoting participatory governance to empower local communities. Sustainable land practices can support marginalized communities' environment and livelihood by integrating traditional ecological knowledge into policy-making. A collaborative approach involving multiple stakeholders in decision-making processes is advocated, aiming to achieve more inclusive and just governance systems while addressing conflicts and promoting resilience among Indigenous and pastoral communities facing economic and environmental challenges.

Introduction

The forced displacement of local communities and Indigenous peoples from their ancestral lands in the name of conservation and development is a pressing issue that has garnered global attention, particularly in developing countries, disrupting their social fabric, cultural heritage, and livelihood (Maddox, *et al* 2023; Indígenas 2023; and Dawson, *et al* 2021). Starting in the mid-20th century, a series of land and wildlife laws aimed at conservation in Northern Tanzania pushed the Maasai off large tracts of their traditional land, including present-day Serengeti National Park (The Oakland Institute 2021; Jama and Mesfin 2024; Goldman 2011).

The Maasai pastoralists have long been custodians of the land, relying on traditional pastoralism for sustenance and cultural preservation. However, the encroachment of external interests often leads to dispossession, marginalization, and the erosion of centuries-old cultural practices (IWGIA, 2022a; Jama & Mesfin, 2024; THRDC, 2023). The displacement of these communities exacerbates existing inequalities, perpetuating cycles of poverty and insecurity. The stark contrast between the interests of local communities seeking to maintain their way of life and external actors prioritizing economic gains underscores the complexities inherent in land ownership struggles.

The history of Tanzania's Land Tenure System and its legal frameworks

Tanzania's land tenure and laws can be traced back to the colonial era, particularly the time between 1884/85 and 1917 and 1918 to 1961 for German and British administrations, respectively (The Oakland Institute 2021). During the Germans era, the Land Decree was passed, allowing all territorial land to become crown land controlled by the German Empire, investing the power over land to a governor as a "custodian" permitting him to take away the land for certain uses assumed of the public interest (Shaudo *et al.* 2022). Under this decree, any land without evidence of ownership or continued use is considered vacant and ownerless. In 1903, the Land Registration Ordinance was passed, allowing the land to be allocated to individual, mostly white settlers through the land registration bureau. Although the bureau allocated the land to the white settlers, traditional and Indigenous lands were recognized as they fell under the village boundaries (Shaudo *et al.* 2022).

In 1923, Land Ordinance No.3 was passed, declaring all land public and giving a governor the power to control the natives' lands for the "use of common benefit," leading to the local communities losing large areas of land to the government (The Oakland Institute 2021). Between 1923 and 1926, the traditional communities lost approximately 120,000 hectares of land to foreigners (Barume 2010).

In 1940, the Game Ordinance was enacted to create the national parks and reserves, including setting the original boundaries of Serengeti National Park and imposing the first restrictions on settlement and use of the surrounding lands (The Oakland Institute, 2018). Later, in 1957, the community of inquiry led by the British recommended that the existing Serengeti National Park be split into two, whereby the first part is the present-day Serengeti National Park(SENAPA) and the second part became the famous Ngorongoro Conservation Area (NCA). They further recommended the total restriction on human habitation, including the Maasai (natives of the land) in the first part, while the latter allowed multiple land use with three goals of conservation, tourism, and protecting the interest of Indigenous groups (Shaudo *et al.* 2022; Fraser 2019). The National Parks Ordinance in 1959 led to the Maasai losing their customary rights, forcing them to other lands such as far east to Ngorongoro and Loliondo areas (Fraser 2019; Shivji and Kapinga 1989; Lissu 2000).

Additionally, the NCA Ordinance of 1959 established the Ngorongoro Conservation Area, allowing the Maasai settlement rights with the Ngorongoro Conservation Area Authority (NCAA) as the governing body. The NCAA was given the ability to prohibit, restrict, or control various activities in the region, including cultivating land, grazing cattle, and creating settlement dwellings (Shaudo *et al* 2022).

Through the Arusha manifesto of 1961, the government pushed wildlife conservation with a bold promise of dedicating more land for conservation and wildlife parks, creating a specific role for international conservation groups to provide technical expertise in the planning and management of conservation areas in Africa (The Oakland Institute 2018; Burnett and Conover 1989). These groups, such as Frankfurt zoologists and the International Union for Conservation of Nature (IUCN), later lobbied to restrict the rights of the Maasai to cultivate, graze, and move within their residence (Shaudo, *et al* 2022; Fraser 2019; Burnett and Conover 1989). In 1974, the Wildlife Conservation Act was passed, creating three types of conservation lands *(GCA, wetland reserves, and Wetland areas)* in addition to the game and parks, with significant restrictions placed on activities within these areas.

The vital legislation on land governance and tenure is the 1999 Land Act & Village Land that replaced the 1923 Land Ordinance, categorizing Tanzania Land under three categories, namely general land, village land, and reserved land (Veit 2019; URT 2022). Although the Village Act No. 5 of 1999 recognizes customary tenure and empowers village authorities to manage lands, many communities still lack security in their customary land, with the president holding the power to declare the village land under other categories of land for what is called "public interest" the same way the 1923 land ordinance did (Gailo, *et al* 2014; Jama and Mesfin 2024).

Losing their land: Eviction of the Maasai from their Lands from 1940s -2023

The Maasai have inhabited the Serengeti plains and the Ngorongoro highlands since the 15th century, even before the Swahili trader's encounter in the 17th Century. They were expelled from their homeland when

Serengeti was made a National Park towards the end of the colonial period (Arhem 1985; Faurler 1882; Lissu 2000).

Contrary to some claims that the Maasai were offered Loliondo for Serengeti, they have inhabited it since time immemorial (Pearsall 1956; The Oakland Institute 2021). During the negotiations for the relocation of their relocation from the Serengeti plains in 1948, the British made a solemn to them that they had a right to be consulted, engaged, heard, and respected on matters related to land rights, with the promise of not breaking that pledge (Shaudo, *et al* 2022; Shivji and Kapinga 1998). Referring to the Ngorongoro Conservation area, when addressing the Federal Council of the Maasai people in 1959, Richard Turnbull, the British governor of Tanganyika, stated that;

> " ...should there be any conflict between the interests of the game and the human inhabitants, those of the latter must take precedence" (Shaudo, et al 2022)

The laws that established the NCA in 1959 did not extinguish the customary land rights of Indigenous residents but rather preserved them. In this view, the Maasai in NCA are, therefore, rightful landholders under the deemed customary right of occupancy (Shaudo, *et al* 2022; Shivji and Kapinga 1998).

After the failed evictions in the Loliondo and Ngorongoro areas, the government, in the middle of 2022, initiated the military operation to demarcate and evict residents living within the 1502 Km^2 along SENAPA, affecting about 15 villages in Sale and Loliondo Divisions, paving a way for the establishment of Pololeti Game Reserve. Moreover, the residents of NCA were forcefully relocated to more than 600 kilometers away in the Handeni District in the Tanga region (Shaudo, et al. 2022; IWGIA $2022_{a;}$ IWGIA 2022_{c}).

What does this eviction mean for the social, cultural, and economic well-being of the Maasai Pastoralist?
In the words of Matthiessen (1972), the African landscape is not just a backdrop but a living entity that shapes the lives, cultures, and survival of its inhabitants. The Maasai and their cattle depend entirely on land for pasture and hence family livelihood (Jama and Mesfin 2024; Rabinovich *et al* 2022). Shaudo, *et al* (2022) highlighted the connection of the land to the community livelihood and economic implications, cultural ties, and loss of their Identity. The ongoing restriction and forceful relocation have led to the community suffering from hunger, absolute poverty, violation of human rights, social conflicts, loss of land access and user rights, disruption of social structure, and limited community cohesion (UN 2022; Shaudo *et al* 2022; THDRC 2023). The Maasai lost most of the irreplaceable ceremonial and ritual sites affecting the community's belonging and identity with no opportunity to practice their culture, rituals, and traditional ceremonies such as rites of passage and rites of retirement, which are vital for their identity and tradition.

Additionally, the loss of access to fertile land led to serious consequences, resulting in poverty and starvation, limiting their economy and exacerbating vulnerability (Jama and Mesfin 2024; Sørensen and Vinding 2016). Shaudo *et al* (2022) reported that the Maasai pastoralists evicted from the Mkomazi Game reserve have experienced livestock loss, leaving them in dire poverty, and their fate might be shared by those of Ngorongoro. Due to a lack of enough fodder and grazing areas, the evicted Maasai have lost 70 –100% of their herd, leaving them in absolute poverty (Gailo *et al* 2014). Wickham *et al* (2014) highlight that due to climate variability, diseases, inadequate grazing and water resources, and unsuitable conditions for livestock keeping around the villages, they re-settled the Maasai and lost 95 percent of their livestock.

Conclusions and recommendation
One might ask, what then is there for the pastoralist communities in Tanzania? One should understand the reason behind this dilemma. Factors such as poor land use policies, political will in respecting the existing legal frameworks, fortress conservation, and the underlying impacts on the pastoralist communities. Most of the lands have no title deeds making it more easy to be taken by the state.

Addressing the challenges faced by the Maasai requires a comprehensive understanding of the complex interactions between social, economic, and environmental factors. With the major factor of displacement and forceful relocation from their homes being wildlife conservation backed by the state, the move has failed to take into consideration the far greater impacts on the community and existing relationship with their natural environment

The governing bodies should consider local communities' participation, encourage sustainable land management practices, foster community resilience, and respect Indigenous people's rights. There is a need for friendly and inclusive policy frameworks that allow pastoralist communities to engage and participate in land use plans and have a say on matters related to their land.

Acknowledgments
Special thanks to the African Youth Pastoralist Youth Initiative (AYPI) and Global Communities (Afriscout) teams for their support and input on the study. Special Thanks to Dr. Reguli Mushy for the time he dedicated to review and technical guidance.

History of the Pastoral Board of South Australian and the *Pastoral Land Management and Conservation Act 1989.*

Maconochie JR [1]; Nicolson AB [1]; Peacock, S [1]

[1] Pastoral Land Management Branch, Department for Environment and Water, Government of South Australia.

Key words: Pastoralism; Conservation; Board; Act; Sustainability

Abstract
South Australia's Pastoral Board (the Board) has a vital role in overseeing the sustainable management and conservation of the state's pastoral lands for a diverse range of uses, which continue to evolve over time as new markets and industries emerge, as the climate changes and communities evolve.

Pastoralists and other land managers play a critical role in managing and conserving vast areas of the state's land which holds both productive and ecological values as well as cultural and social values.

Originally formed under the Pastoral Act of 1893, the Pastoral Board of South Australia has a long history and extensive experience in the administration of pastoral land (Donovan P. 1995). The current *Pastoral Land Management and Conservation Act 1989* enables the Board to manage land in a contemporary context.

The Act aims to:

- ensure that all pastoral land in the State is well managed and utilised sustainably;
- provide for monitoring of land condition, prevention of degradation and rehabilitation of the land;
- provide a form of tenure suitable for the pastoral industry (42-year leases reviewed every 14 years);
- recognise and provide for the rights of Aboriginal people to follow traditional pursuits on pastoral land; and
- enable community access to and through pastoral land.

The Board aims to achieve the world's best managed pastoral country, by working with pastoral land managers and communities to develop, adopt and promote practices that sustain the state's pastoral lands for current and future generations.

The Board's immediate priorities include delivering an effective and fit for purpose land condition assessment program, effective compliance, and sound policies informed by community input, to support certainty for pastoral lessees, and reduce risks of degradation that affects the long-term sustainability of pastoral lands. It works closely with other regulators to achieve aligned management for a range of outcomes, including complementary legislative regimes for new industries.

Introduction

The *Pastoral Land Management and Conservation Act 1989* (the Act), and the establishment of the Pastoral Board of South Australia, mark transformative points in the history of land management and conservation in South Australia. Together, they represent a governmental commitment to addressing the complex demands of pastoral land use in one of the world's most arid and ecologically sensitive regions. South Australia's pastoral industry, a cornerstone of the state's economy since the mid-19th century, has historically centered on grazing in vast, arid and semi-arid landscapes. While pastoralism contributed significantly to economic growth and settlement, the expansion of grazing activities into semi-arid and arid regions led to severe environmental consequences, including soil erosion, vegetation loss, and ecosystem disruption (Donovan 1995).

In response to these challenges, the Act introduced a comprehensive legal framework aimed at balancing economic interests with sustainable land use and environmental conservation. This landmark legislation empowered the Board with responsibilities that include overseeing land leases, monitoring ecological health, and ensuring compliance with sustainable practices. The Act was notable for its emphasis on conservation principles, promoting practices that would protect biodiversity and preserve the natural resources critical to both the pastoral industry and regional ecosystems.

Pastoral Land Management and Conservation Act 1989

The *Pastoral Land Management and Conservation Act 1989* represents a significant legislative milestone in South Australia's efforts to manage its arid and semi-arid lands sustainably. This Act was introduced as a comprehensive response to the unique environmental, economic, and social challenges of pastoral land use in a state where extensive grazing is a critical economic activity but one that often conflicts with ecological preservation. Prior to this Act, pastoral land management in South Australia was governed by earlier regulations that largely focused on promoting agricultural expansion and economic development, often at the expense of environmental sustainability. Over time, however, it became clear that these policies had led to issues such as land degradation, biodiversity loss, and the depletion of essential resources.

The Act reshaped the legislative framework, introducing measures that prioritised both economic viability and ecological integrity. By emphasising sustainable land use, biodiversity conservation, and responsible resource management, the Act sought to address the long-term health of South Australia's pastoral regions. It established the Board as a key regulatory body with authority over land leases, monitoring, and the enforcement of sustainable practices. The Act also promotes collaboration between the government, pastoralists, and environmental organisations, fostering a more holistic approach to land management. The advent of renewable energy has seen amendments to the legislation allowing for establishment of other land uses such as wind and solar farms and hydrogen projects.

Pastoral Board Establishment

The Pastoral Board (the Board) has played a pivotal role in shaping the state's pastoral landscape, evolving in response to environmental, economic, and social changes since its inception. Established in 1895, the Board was initially appointed to manage the allocation, leasing, and regulation of vast tracts of land used for grazing in South Australia's arid and semi-arid regions. As settlers expanded into harsher, less hospitable areas, issues of land degradation, overgrazing, and water scarcity began to surface. The creation of the Board was a government initiative aimed at addressing these challenges by overseeing land use, ensuring sustainable practices, and balancing economic interests with environmental stewardship. Over time, the Board's responsibilities expanded, adapting to changes in agricultural technology, environmental policy, and indigenous land rights. Its policies and regulations have had lasting impacts on South Australia's land use patterns, biodiversity conservation, and rural communities.

Pastoral Board Today

The Board consists of six members from diverse backgrounds appointed by the Minister under the Act for a 3-year term, which can be renewed. Each member brings a distinctive skill set to the Board's deliberations.

Collectively the Board has an extensive knowledge of the administrative, environmental and economic issues of the South Australian pastoral lands (Pastoral Board of SA, 2023).

The Board administers pastoral leasehold tenure on 322 pastoral leases over 40% of the state (approximately 422,000 km^2). The Board is a statutory authority responsible to the Minister for Climate, Environment and Water in administration of the Act for:

- managing and enforcing lease terms and conditions
- supervision of the pastoral lease system
- defining management conditions, including the number and types of stock to be managed
- assessing and reporting on the condition of leased land
- implementation of property plans and other measures to prevent land degradation
- managing and recording submission of annual stock returns
- producing an annual report
- assisting the Valuer General in determining pastoral lease rents
- administration of the Pastoral Land Management Fund
- administration of alternative land uses for pastoral land
- providing advice to the Minister on policies and other general advice.

In discharging its responsibilities, the Board must have regard to plans or guidelines of other relevant government bodies, and to the terms of any Indigenous Land Use Agreement (ILUA) on pastoral land. The Board has established a Strategic Plan which guides its direction and priorities to meet its legislative responsibilities, and community and industry expectations (Pastoral Board of SA, 2023). The plan outlines the Board's vision, goals and strategic outcomes and was developed through consultation with key stakeholders. The work of the Board is supported by the Pastoral Land Management Unit (Pastoral Unit) based in the Department for Environment and Water. The Strategic Plan provides guidance for the Pastoral Unit in supporting the operation of the Board.

One of the Board's primary responsibilities is to oversee the lease agreements, which outline sustainable land use practices and set conditions for grazing activities on state-owned pastoral lands. This is achieved through regular inspections and assessments carried out by the Pastoral Unit. The Act requires that the Board must conduct land condition assessments at least once every 14 years for each pastoral lease.

The Board ensures that leaseholders adhere to environmental standards, helping to prevent overuse and degradation of land. The Board also collaborates with stakeholders, including pastoralists, environmental agencies, and indigenous groups to foster a cooperative approach to land management. The Board works closely with other regulators to achieve aligned management for a range of outcomes, including complementary legislative regimes for new industries (Pastoral Board of SA, 2024).

In addition to its regulatory functions, the Board serves an advisory role, providing resources and support to pastoralists to promote conservation practices that align with both economic productivity and environmental sustainability. This includes facilitating relevant research, advocating for land management innovation, and promoting best practices that enhance landscape resilience in the face of climate variability and other pressures. By focusing on sustainable practices, the Board aims to maintain the ecological health of South Australia's pastoral lands, ensuring their viability for future generations, and aspires to achieve the world's best managed pastoral country.

Abstract

Food and nutrition security represents one of humanity's most significant global challenges. Rural communities in developing countries depend on edible wild plants to fulfill their nutritional needs during periods of food scarcity. The objectives of this study are: a) to review the existing information regarding the nutritional contributions of wild edible plants, and b) to assess the role of women in the utilization of wild edible plants as food in rural communities within the Shahrood region of Iran. Semi-structured interviews and participatory observations served as the data collection methods. The data were analyzed using usage report indicators. A total of 1,086 use reports were compiled from 44 interviews (20 men and 24 women), covering 67 wild edible plants and one fungus consumed by local communities. Knowledge of wild edible plants was greatest among women, comprising a total of 646 usage reports. Three species-*Allium iranicum* (Wendelbo) Wendelbo, *Mentha longifolia* L. Huds, and *Allium umbilicatum* Boiss-with reports numbered 75, 66, and 65 respectively, accounted for the highest usage reports. Our findings emphasize the significance of women's traditional knowledge in utilizing wild edible plant resources in this region.

Introduction

Wild edible plants (WEPs) are usually considered to constitute all plant resources that are neither cultivated nor domesticated (Biri et al. 2024). These plants grow in many different habitats (Wang et al. 2020; Khakurel et al. 2021) and play a vital role in ensuring food security for countless families around the world (Biri et al. 2024). Some rural communities in mountainous areas rely on these plants to meet their nutritional needs (Khakurel et al. 2021; Jalali et al., 2024) These plants and the food they produce are integral to the cultures of these societies, playing a crucial role in their lives (Jalali et al. 2024). WEPs assist the livelihoods of the local people in energy sources, construction, medicines, ecological services, aesthetics, income generation, and household utensils (Anbessa et al. 2024). They are also regarded as a means of survival for these local communities, particularly during times of drought, famine, and danger (Wang et al. 2020), Studying these plants is necessary not only to preserve ethnobotanical knowledge but also to conserve their populations genetic resources (Khakurel et al. 2021). Many ethnobotanical studies have shown differences in the knowledge and practices held by men and women (Acosta-Naranjo et al. 2021). Decades of ethnobotanical observations have shown that knowledge varies significantly according to the identity attributes of participants, such as their religion, occupation, status, income level, geographic origin, and gender (Wall et al. 2018).

Iran is an ecologically diverse country with exceptionally rich botanical diversity (Noroozi et al. 2019). Many plant species in Iran are used for human consumption, most of which fall under the broad category of WEPs (Jalali et al. 2024). The food and nutritional contribution of WEPs has not been fully investigated in Semnan Province. Therefore, the objective of this review is to explore available information about WEPs nutritional contribution and examine the role of women in the use of WEPs in Semnan Province.

Methods

Study area and ethnobotanical data collection

The study area is located in northeastern Iran in the Semnan Province, Shahrood municipality, in the Bastam rangelands (36°33′41″–36°35′37″ N and 54°40′39″–55°32′39″ E). Ethnobotanical data were compiled through semi-structured interviews during field walks guided by informants and participatory observations. During these guided field walks, the informants were asked information about the collection and utilization of WEPs. A total of 44 informants were selected from 12 villages: 3 from Tash, 4 from Negarman, 11 from Abarsij, 2 from Ali Kahi, 1 from Hosseinabad, 3 from Meyghan, 3 from Qaleh Now-e Kharaqan, 3 from Proo, 7 from Abr, 4 from Khij, 2 from Mazj, and 1 from Gilan. Among the informants were 11 males and 13 females (see Fig. 1).

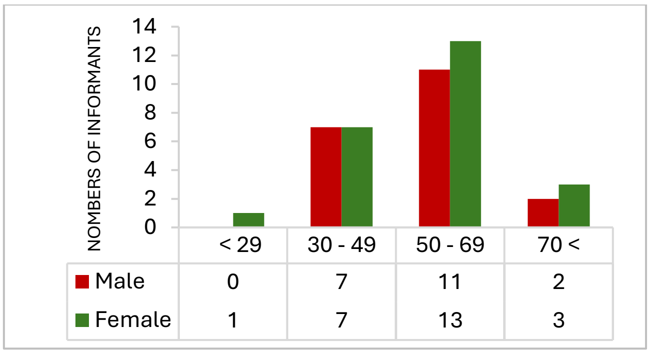

Fig 1. Age distributions of informants.

Data Analysis

The collected data were structured using reports in an Excel spreadsheet. The ethnobotanical importance indicator, including the use report, was calculated. Analyses were done using the ethnobotany R package in R.

Results

Diversity of WEPs in the study area

The 44 informants (20 men and 24 women) reported a total of 66 WEP species and one fungus from 54 genera and 24 families. Ethnobotanical information about these plants, including food categories and use reports, is listed in Fig. 3, while Fig. 4 (B) shows images of some WEPs found in the study area. A total of 1,086 use reports were documented from 44 interviews, of which 440 were related to men and 646 were related to women, as shown in Fig. 2 (A).

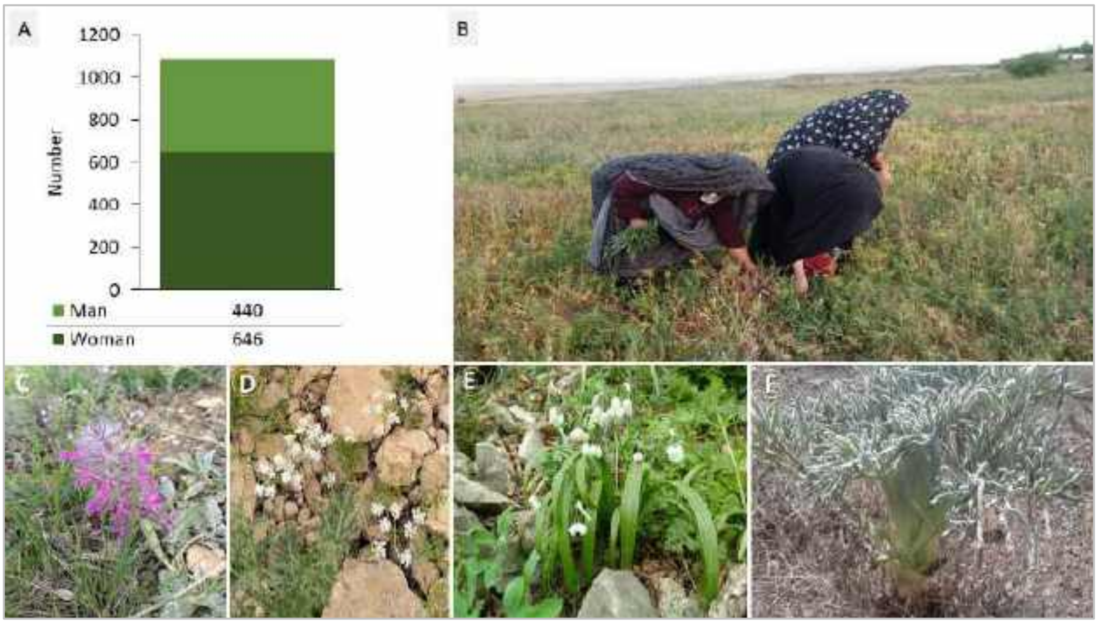

Fig 2. (A). Indicator of use report of plants (UR), (B). Collection of WEPs by rural women, and pictures of some WEPs in the study area: (C). *Stachys lavandulifolia*, (D). *Elwendia cylindrica* (Boiss. & Hausskn.) Pimenov & Kljuykov, (E). *Allium paradoxum*, (F). *Ferula foetida* (Bunge) Rege.

Dietary diversity

In this study, 1086 consumption reports based on the eating habits of people in the study area were classified into thirteen usage categories (Fig. 3). Among these categories, rice vegetable was the most cited consumption category with the most usage reports (37 species, 268 usage reports, 24.7%) (Fig. 4, Bb). By rice vegetable, we refer to WEPs that are prepared by boiling and mixed with rice dishes, followed by coco sabzi (28 species, 186 use reports, 17.1%) (Fig. 4, Ba). Coco sabzi is a traditional dish made from WEPs fried with eggs and spices. soup (39 species, 162 use reports, 15%), herb stew (32 species, 120 use reports, 11%), yogurt (16 species, 75 use reports, 7%), kashk (8 species, 71 usage reports, 6.5%) Kashk is a dish made from WEPs combined with dairy (kashk). salad (11 varieties, 47 reports of use, 4.3%), herbal tea (5 varieties, 43 reports of use, 4%), vegetable bread (10 varieties, 40 reports of use, 3.7%) (Fig. 4, Bc), pickled (9 varieties, 23 reports of use, 2.1%), ripe fresh fruit (9 types, 23 usage reports, 2.1%), snack (10 types, 22 usage reports, 2%) and finally jam (3 species, 6 reports of use, 0.5%).

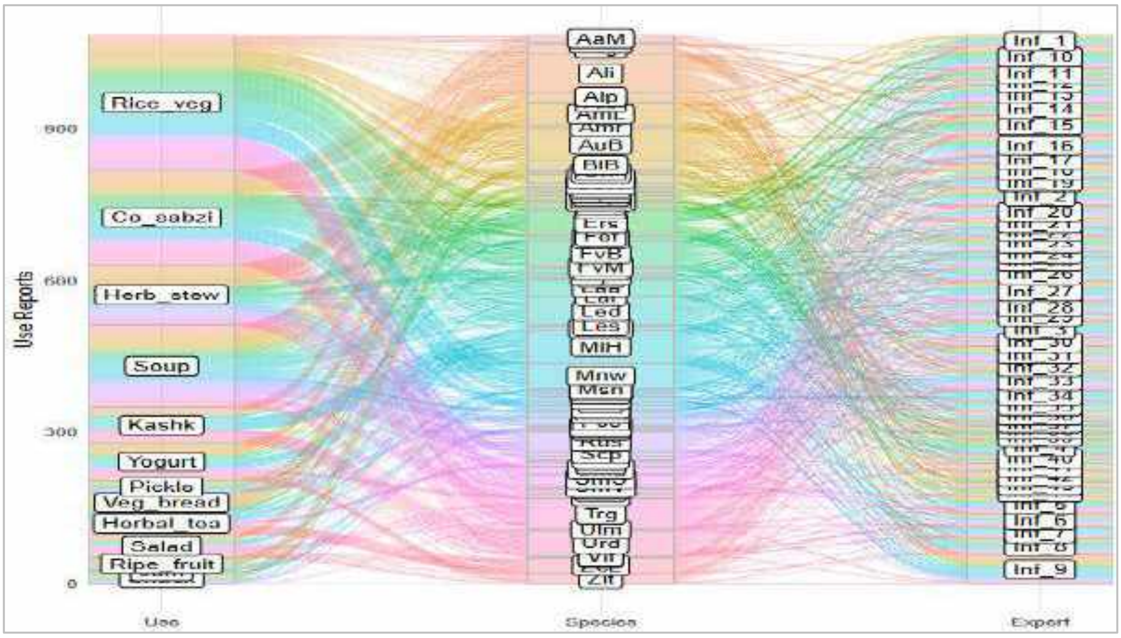

Fig 3. Usage report (UR) of 67 WEPs for 13 different food categories by 44 interviewees in 12 villages of Semnan, Iran.

Gender roles

We found differences in the total number of known WEP species and used reports between genders (Fig. 2, A, and 3). The respondents explained that women play a prominent role in using wild plants, as they are easily accessible around the village, and rangeland (Fig. 4, A). However, men showed greater knowledge of species in forested areas due to greater access to forested areas for their work.

Fig 4. A). Women collect wild edible plants for nutritional purposes, B). Food prepared from WEPs that are ready for consumption: (a). Coco sabzi, young leaves of *Allium grande Lipsky*, (b). Rice vegetable, leaves of *Eremurus* sp., and (c). Bread, different organs of *A. iranicum*.

Discussion

The importance of wild plants in feeding rural populations is widely recognized through various studies (Anbessa et al. 2024; Jalali et al. 2024). In our study region, the WEPs showed a wide range of variation, not only in the number of species but also in different categories of consumption for nutritional purposes. When compared to other studies (Luo et al., 2019). However, our research uniquely documented the use of these plants across 13 different nutritional categories, with a significant emphasis on the role of women in utilizing these plants, which has not been reported in studies conducted within Iran. The local people's WEPs collection calendar demonstrates valuable indigenous knowledge rooted in their rich culture of edible plant utilization. These species are facing growing threats such as over harversting, drought and grazing, emphasizing the urgency of implementing stronger protection measures and adopting sustainable management practices.

Notably, our study sheds light on how collaborative activities in rural settings are especially important for women. Despite the gender imbalance in studies of neighboring countries (Hussain et al., 2023), due to religious and patriarchal family structures, which prioritize males as family heads and resource holders, our study of ethnographic knowledge has shown an important role of women in this field. They actively participate in the collection and utilization of WEPs and contribute to the seasonal household economy by using WEPs as a supplemental food source. Also, women are the primary decision-makers for food preparation in study area and can get to know more plants through gathering and cooking. Gender equality is seen as a goal and a means in achieving the Sustainable Development Goals (SDGs) (Duflo 2012). Overall, our study shows that these species play important role in household diets and have great potential to contribute to food and nutritional security. However, these results show the major contribution of women in linking knowledge between the food cultural domains. The women continue to play a key role in maintaining gastronomic cultural heritage in present days.

Adaptation strategies of pastoralists to degradation of Banni grassland in India through livelihood diversification

Manjunatha, BL[1]; Sureshkumar, M[2]; Hajong, D[3]; Tanwar, SPS[4]

[1,2,3,4] Central Arid Zone Research Institute, Jodhpur, Rajasthan, India (Indian Council of Agricultural Research, Ministry of Agriculture and Farmers Welfare, Government of India).

Key words: Arid region; *Banni* buffalo; income security; livelihood security; *Prosopis juliflora*.

Abstract

Pastoralism is the predominant livelihood in *Banni* grasslands. However, combination of factors (livestock population pressure, overgrazing, severe droughts, rapid invasion of *P. juliflora*) has led to severe degradation of the grasslands. This has increased the risk of pastoralism as a profitable and sustainable livelihood. In this context, this socio-economic study investigated the livelihood diversification process adopted by pastoralists in *Banni* grasslands. Primary data were collected from 280 households from 13 villages using stratified random sampling technique. Out of these, detailed livelihood diversification analysis of 50 households (case studies) was undertaken. Results found that pastoralists diversified into combination of eight non-pastoralism based livelihood options (charcoal production, labour, services, leather work, embroidery work, honey & gum collection, tourism and trade) for livelihood security. Based on the combination of pastoralism and other income generating activities, there were eight different household typologies in the region viz., (i) Buffalo rearing + 7 activities (66%); (ii) Buffalo & Goat rearing + 1 activity (4%); (iii) Buffalo + Cow rearing + 3 activities (4%); (iv) Cow rearing + 2 activities (4%); (v) Camel rearing + No additional activity (2%); (vi) Sheep & Goat rearing + 1 activity (4%); (vii) Goat rearing + 5 activities (12%); and (viii) 5 activities without any livestock (6%).

The adaptation strategies of pastoralists to degradation of *Banni* were reduced dependency on pastoralism (reduction in herd size of buffaloes, moving out of buffalo rearing, goat rearing in small herds) and diversification into non-pastoralism based livelihood options. Buffalo rearing households earned highest annual income. Goat rearing and livestock-less households were the poorest. It indicated that moving out of pastoralism (even after income diversification efforts) was associated with low incomes. Therefore, increasing the carrying capacity of the grasslands through scientific management and development of supply and value chain are the most sustainable options for risk reduction and enhancing income of households.

Introduction

Banni grassland in Kachchh district of Gujarat in India is a socio-culturally unique and ecologically significant ecosystem. Agriculture is not practiced in the grassland and pastoralism is the main livelihood option for more than five centuries (BCPMB 2010, RAMBLE 2024, *B*anni 2024). However, significant changes in the recent past such as the declaration of *Banni* grasslands as Protected Forest, rapid invasion of *P. juliflora*, salinity ingress, successive and severe droughts, increase in livestock population and overgrazing have led to its' severe degradation (Safriel and Vijay Kumar 2021, Manjunatha et al. 2022, Singh et al. 2023). *Banni* grassland once covered an area of 3800 sq. km (Bhandari 1990) but decreased to 2618 sq. km (Rawat and Adhikari 2015).

Banni grassland is a heterogeneous ecosystem, which has wetland, grassland, and dryland habitats. Forest department introduced *P. juliflora* (a shrub native to Mexico and South America) in 1960's to stop the advancement of Rann. However, the invasion of *P. juliflora* is slowly converting it to shrubland (Sharma et al. 2024). Further, there is a shift in livestock composition in favour of buffaloes over cows. The livestock population in *Banni* grasslands during 2021-22 is estimated to be 1,01,235 heads with the composition of buffalo, cattle, sheep and goat at 77, 13, 5 and 5% of the population respectively (Projected from Manjunatha et al. 2019a). These ecological and policy changes along with increased access to organized dairy industry have contributed to the gradual shift from migratory pastoralism to semi-migratory and sedentary animal husbandry. In this context, the objective of this study was to understand the adaptation strategies of the pastoralists to mitigate the impact of degradation of *Banni* grassland on their livelihood security.

Methods

Research design: An ex-post facto survey research design and case study method were used.

Locale of the study, sample and sampling procedure: *Banni* grassland located in Bhuj taluka (subdivision) in Kachchh district of Gujarat State in India was purposively selected as the study area. Thirteen villages were selected for the study using stratified sampling technique to represent different parts of *Banni*.

Data collection tools and analysis: A structured interview schedule was developed for the study. The primary data were collected between January 2015 and June 2017 by personally interviewing 280 households selected randomly from these 13 villages. Out of these, detailed livelihood diversification analysis of 50 households was undertaken using case study method. The primary data collected from pastoralist households were supplemented and validated with other research techniques such as participant observation, Focussed Group Discussions (FGDs) and synthesis of secondary data. Extensive field visits were made to *Banni* grasslands and pastoralists' livestock yards at their home and during migration. Charcoal production units were visited. Embroidery and leather work units were visited at the selected respondents' houses and exhibition stalls during *Rann Utsav* (A tourism event organized by the Government of Gujarat every year at Rann of Kachchh). FGDs were held with key pastoralists in each village and other stakeholders such as representatives of the *Banni* region (Banni Breeders Association) and researchers and organizations working on *Banni* grasslands. Annual incomes were calculated for the agricultural year 2016-17 based on the prices prevailing in the *Banni* region in April 2017 (Manjunatha et al. 2019b). The guidelines on methods for estimating livestock production and productivity developed FAO were followed (FAO 2018).

Results

Upto 94 percent households in Banni grassland were associated with pastoralism/ animal husbandry. The adaptation strategies adopted by pastoralists to reduce the impact of degradation of Banni grasslands were reduction in herd size of buffaloes, moving out of buffalo rearing, goat rearing in small herds and diversification into non-pastoralism based livelihood options. The pastoralists diversified into combination of eight non-pastoralism based livelihood enterprises (charcoal production, labour, services, leather work, embroidery work, honey and gum collection, tourism and trade) for livelihood security. Based on the combination of pastoralism and other income generating activities, there were eight different household typologies in the region viz., (i) Buffalo rearing + 7 activities (66%); (ii) Buffalo & Goat rearing + 1 activity (4%); (iii) Buffalo + Cow rearing + 3 activities (4%); (iv) Cow rearing + 2 activities (4%); (v) Camel rearing + No additional activity (2%); (vi) Sheep & Goat rearing + 1 activity (4%); (vii) Goat rearing + 5 activities (12%); and (viii) 5 activities without any livestock (6%).

Rearing of Banni buffaloes along with other livelihood options was the dominant typology (Figure 1). Households rearing cows and camels exclusively were very few in number (6%) but their incomes were equivalent to buffalo-rearing households. Buffalo/cow/camel rearing households represented traditional pastoralist households and they earned >70% of their income from pastoralism/animal husbandry (Figure 2). Migratory sheep rearing involving large herds (with few goats in the herd) is a traditional occupation practiced by poor pastoralists. Backyard goat rearing in small herds is a relatively recent extra income generating activity practiced by poor households. It is an indication of shifting away from traditional pastoralism and lack of ownership of buffaloes, cows, camel and sheep. Livestock-less households represented extreme end of continuum who have completely shifted away from pastoralism. Goat rearing and livestock-less households constituted 18% households and earned their major income from non-pastoralism based activities (charcoal production, unorganized services and labour). Goat rearing and livestock-less households were the poorest indicating that moving out of pastoralism (even after income diversification efforts) was associated with low incomes. Charcoal production is mostly based on cutting of *P. juliflora.*

Households engaged in buffalo-based pastoralism earned highest annual income and had choice to engage in high-income generating livelihood options such as tourism and trade. Livestock-less and goat-rearing households earned lowest annual income and were dependent on low-income generating activities such as charcoal production, unorganized services, labour and honey and gum collection for want of better employment opportunities.

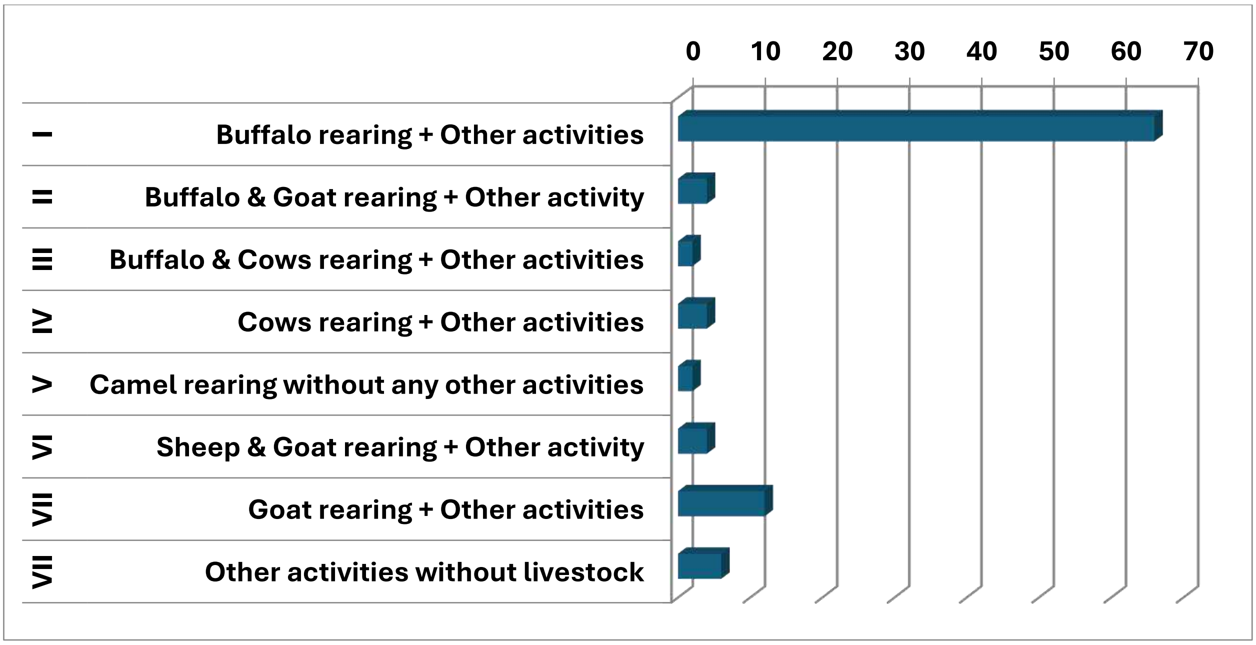

Figure 1: Household typologies and livelihood diversification adopted by pastoralists in Banni grasslands

Note: "Activities" indicate "income generating activities". The terms "income generating activities" and "livelihood options" are used interchangeably in the article.

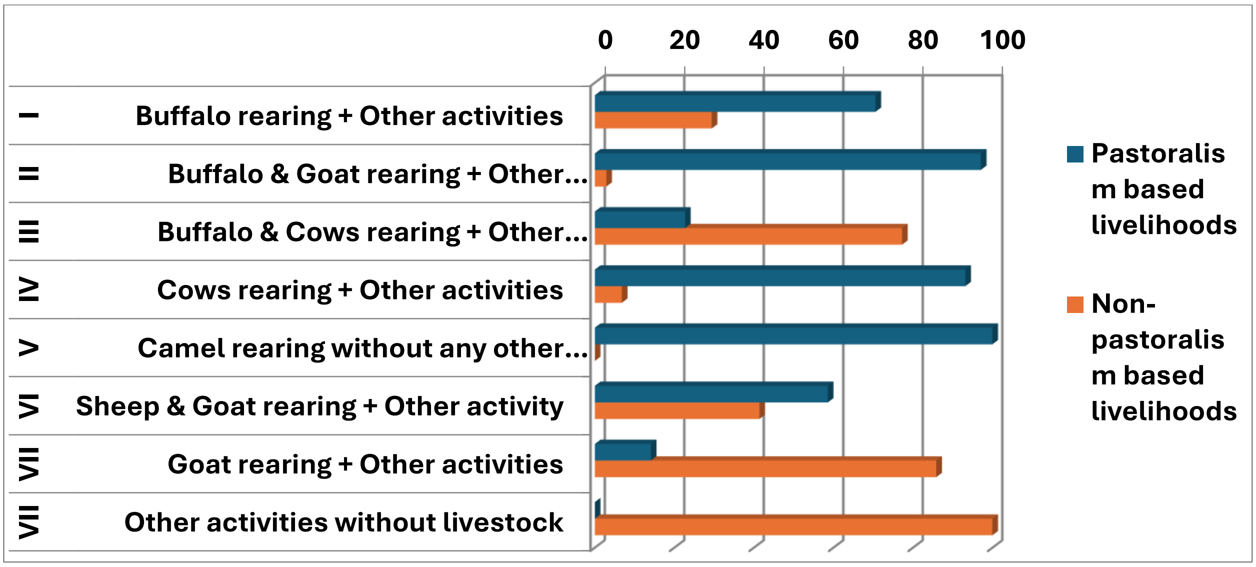

Figure 2: Share of pastoralism and non-pastoralism based livelihood options in average annual net income (%) for different household typologies in Banni grasslands

Discussion

Pastoralism/ animal husbandry as a remunerative and sustainable enterprise in *Banni* grassland is under severe pressure due to its degradation. The reduced carrying capacity has increased the cost of livestock rearing as the fodder shortage is being compensated by purchase of feed and fodder resources from market. Therefore, 98% pastoralist households have integrated non-pastoralism based livelihood options for income and livelihood security as an adaptation strategy. At the same time, the remunerative employment opportunities in secondary and tertiary sector are very limited in the region. Therefore, households shifting away from pastoralism are forced to opt for livelihood options which are less remunerative than the pastoralism/ animal husbandry itself.

Pastoralism in India is invisible in government policies and programmes since there is no authentic data available about the numbers, livestock and economic contribution of pastoralism. The 21st Livestock Census 2024, for the first time plans to include a separate enumeration of pastoral livestock which marks a significant step towards designing targeted interventions and public investment/schemes (Bhatti 2024). Grasslands are frequently ignored in sustainable development objectives. Adequate knowledge of how grassland degradation affects ecosystem services is essential for sustainable management and grassland ecological restoration (Dey et al. 2024). Ecological restoration of the grassland requires scientific management involving participation and engagement of the pastoral community and community based organizations at all levels of decision making. From 2019 to 2023, *P. juliflora* was uprooted with JCB earthmovers restoring 3000 hectares, thereby increasing vegetation species richness by 12% and tripling biomass productivity. Innovative income generation efforts such as sale of carbon credits generated from biochar production from *P. juliflora* were undertaken for sustainable management of the grasslands and economic stability of the pastoral communities (Pokar 2024).

Acknowledgements

We acknowledge the ICAR-Central Arid Zone Research Institute (CAZRI), Jodhpur, Rajasthan, India (Indian Council of Agricultural Research, Ministry of Agriculture and Farmers Welfare, Government of India) for funding and logistic support for this project. We sincerely thank the Hon'ble Director, ICAR-CAZRI for his guidance and constant support at all stages of this project. Authors also thank the pastoralists in *Banni* grasslands (the respondents) for sharing the information and data for this study.

Enabling public access to South Australia's pastoral lands

Nichols, C; Yates, M

[1] Department for Environment and Water, South Australia

Key words: rangelands; public access; pastoral; South Australia

Abstract

South Australia's pastoral lands are a rich resource of unique landscapes and Aboriginal and European heritage, drawing visitors from across the world to experience these amazing locations alongside commercial pastoral businesses.

The Pastoral Land Management and Conservation Act 1989 (the Act) enables access to pastoral lands:

- the public can access any pastoral lands with consent from the pastoral leaseholder,
- Aboriginal people have the right to access pastoral land to carry out traditional practices, in accordance with non-exclusive Native Title, which exists over most pastoral leases,
- Public Access Routes enable public access to significant sites of high value without requiring leaseholder consent.

The Pastoral Board has established a network of 23 Public Access Routes (PARs) totalling more than 700km of tracks to National Parks or historic infrastructure which can only be accessed by passing through pastoral land. These tracks are largely unmonitored and require a 4WD for clearance and access. PARs were initially established in the late 1990s and early 2000s to encourage visitation into the pastoral lands and boost tourism, as well as to develop a remote road network to help connect pastoral lease holders with the broader community.

The SA Government is reviewing the long-term sustainable management of the PAR network to better enable public access to these valuable lands, while mitigating potential risks. This will include reviewing where PARs should be, trends in use, options for maintenance funding, and options for undertaking management of PARs including the role of lessees, government agencies and users. Stakeholders and the broader community will be closely involved during the review.

Introduction

The Pastoral Unit, which sits within the Department for Environment and Water (DEW), supports the Pastoral Board and the Minister for Climate, Environment and Water for the administration of the Act. The Pastoral Unit provides the following support:

- land condition assessments on pastoral land,
- lease condition matters including investigating compliance issues,
- lease tenure dealings (e.g. consents for transfers, mortgages, sub-leasing),
- maintaining operation of the Pastoral Board including communication to or from the board, and

- assistance and advice regarding access to pastoral leases (including public access routes and rights of access for Aboriginal persons).

The South Australian pastoral lands provide a valuable contribution to the economic prosperity of the state. There are 322 leases making up 220 stations over an area of 40 million hectares. This is approximately 40% of South Australia's landmass. Enabling access to these areas provides an opportunity for the public to experience and appreciate complex ecosystems, absorb Aboriginal and European heritage and visit historical infrastructure that helps shape the story of South Australia's transformation throughout time.

Striking the right balance between how, when and where to enable public access to the rangelands access is important. Getting this balance right helps maintain the health of the environment, ensure pastoral activities can be undertaken with minimal disturbance, while also promoting tourism opportunities to unique locations of both historical and conservation value.

There are legislative requirements in place to assist in ensuring access to the rangelands is safe for visitors, respectful for traditional owners, considerate of pastoral lessees and sustainable for the environment. Outside of legislation, the government needs to consider what the desired outcomes are for enabling access to the rangelands. This will help to proactively address possible risks associated with remoteness, isolation, and fragility of the landscape.

Discussion

Access to the rangelands can be achieved through several mechanisms. Each is in place to provide different outcomes for different people and visitors.

Traditional owner access

Aboriginal and Torres Strait Islander people have a deep connection with the land, which is central to their spiritual identity. This connection remains despite the many Aboriginal people who no longer live on their land. Aboriginal and Torres Strait Islander people describe the land as sustaining and comforting, fundamental to their health, their relationships and their culture and identity.

For Aboriginal and Torres Strait Islander people, their traditional Country and what it represents in terms of their history, survival, resilience and cultural and spiritual identity gives them much to take pride in. In the dominant Australian culture, land is thought of as a commodity to be used, enjoyed and owned, or as a place to build a home or grow food or develop a park. Aboriginal and Torres Strait Islander people consider the land differently. This is an important perspective for decision makers to understand to ensure all stakeholder views and beliefs are considered when access to the rangelands is being discussed.

There can be sensitivities around different land use property rights and cultural heritage that have the potential to cause conflicts between land holders and traditional owners if not consulted effectively. One mechanism that is also available to provide traditional owners assurance that they can access culturally significant land and undertake traditional practices is under Section 47(1) of the Act. This section outlines that Aboriginal people have the right to access pastoral land to carry out traditional practices, in accordance with non-exclusive Native Title (Native Title (South Australia) Act 1994), which exists over most pastoral leases. To help defuse possible privacy tensions with pastoralist, the Act prevents camping within a 1km radius of a dwelling or within 500m of a dam or water point.

General visitation

Should a member of the public wish to access part of the rangelands that forms part of a pastoral lease, they must gain consent from the lessee prior to accessing the land. Section 48(3) of the Act set outs the requirements for a person to seek consent of the lessee or the Minister prior to travelling across a pastoral lease, and outlines the penalty for non-compliance with this section of the Act.

This legislative compliance mechanism is an important inclusion to ensure respect of pastoral lessees and their operations are considered when accessing the rangelands, while also providing an opportunity for the public to visit and explore remote areas of the state.

Public access routes (PARs)

The Pastoral Board can gazette PARs under the Act, which provide delineated routes where the public can traverse leased land without needing permission of the lessee. The routes lead to sites of interest, like historical landmarks, infrastructure and National Parks. Before gazetting or revoking a PAR the Pastoral Board must consult with all pastoral lessees affected by the proposal, the relevant regional landscape board and any other interested organisations. No proposals for new PARs have been received since 2011.

The Pastoral Board has established a network of 23 Public Access Routes (PARs) totalling more than 700km of tracks to National Parks or historic infrastructure which can only be accessed by passing through pastoral land. These tracks are largely unmonitored and require a 4WD for clearance and access.

A lessee's rights cease over a PAR. The care, control and management of the routes are vested in the Minister of the Act. However, the Minister is not obliged to maintain the routes, recognising these tracks are in remote areas and there may be limitations in funding available for ongoing maintenance and management of the tracks. There is often a reliance on lessees, PAR users and Park Rangers to provide advice on track condition. PAR users are responsible for adhering to weather warnings and track closures to reduce risks while travelling along PARs. DEW installs signs to identify PARs and notable hazards on the track, and remind users of their responsibilities while on the PAR.

Upon the request of a lessee, tracks can be temporarily closed due to public safety reasons, facilitating stock management or conducting rehabilitation work on adjacent land. Closures are listed on publicly available websites, and the Pastoral Board can require a lessee to erect signs to highlight the temporary closure.

The SA Government is reviewing the long-term sustainable management of the PAR network to better enable public access to these valuable lands, while maintaining the safety of users, and at limited impost to the lessee. This will include reviewing where PARs should be, trends in use, options for maintenance funding, risk management, and options for undertaking management of PARs including the role of lessees, government agencies and users. Stakeholders and the broader community will be closely involved during the review.

Outback roads network

The Department of Infrastructure and Transport (DIT) manage and maintain over 10,000kms of unsealed, outback roads. These roads act as a gateway to the more remote areas of the rangelands, and are an important asset for pastoralism, tourism and other industries like mining and freight. These roads are graded regularly to ensure the network stays in safe condition for all road users. DIT are responsible for maintaining, repairing and upgrading outback unsealed roads to improve road surfaces. Capital works projects can be funded through a combination of South Australian government initiatives and federal funding.

Reasons for visiting the rangelands

Traditional owners may visit the rangelands for cultural reasons, while members of the public travel and visit for tourism purposes, or recreation and leisure activities like four-wheel driving. Some of South Australia's most impressive natural wonders can be found in the rangelands and are often cited as a reason for visiting. For example, Kati Thanda-Lake Eyre, Australia's largest salt lake, is located 770km north of Adelaide. This spectacle provides visitors with an opportunity to set up camp and appreciate the cultural significance this site has for the traditional owners, the Arabana people. Although usually dry, heavy rain events can see the lake come to life, with waterbirds and other wildlife descending into the area.

Rangeland access allows visitors to explore National and Desert Parks, some of which are home to World Heritage Nominated fossil sites, and world-renowned areas like the Flinders Ranges. Maintaining access to these locations encourages tourism, which can benefit state prosperity and growth, while also providing an opportunity to educate visitors on Aboriginal heritage and culture, and the important environmental value that these assets hold.

In more recent times, it has become increasingly evident that, as well as pastoralism, access to the rangelands is important for mining, commerce, and other business ventures, such as the emerging hydrogen and renewable energy industry. Most travel for such ventures is along outback roads, managed by DIT. In addition, some PARs are used as transit routes, which is beyond their scope of use and capacity. They vary in their condition and standard. As part of the current PAR review project, it will be important to explore how these routes can be made safer and more accessible if going to be frequently used for transit and thoroughfare purposes, while also maintaining environmental values. Consideration of an expansion of DITs outback road network could create transport efficiencies, improve economic growth while also increasing public safety.

Some land holders facilitate tourism operations and accommodation for visitors on their leased properties within the rangelands.

Limitations and risks

The South Australian rangelands are home to unique and beautiful landscapes. Care must be taken when travelling in isolated areas like these, as the remoteness and weather conditions can become hazardous quickly. DEW mitigates risks like these by closing the access to Desert Parks between December and March, to reduce the risk of travellers becoming stranded during the hotter months. The PARs that provide access to these sites of interest are also closed to help mitigate the risk. Closures to these areas can be disappointing for keen travellers. Clear communication for the reason for closures is an important part of rangeland access and management.

Given the expansiveness of the rangelands, and the multiple legislative frameworks that govern certain areas, it is sometimes difficult to ascertain the risk profile of an area. If an incident was to occur to a member the public visiting the rangelands, it can be case dependent for who has a duty of care and what personal responsibility the visitor has. Exploration into the minimum standard of the Minister's duty of care within the rangelands will be an important part of the PAR review to ensure PARs are maintained to an acceptable level, as well as ensuring sites of interests are actively monitored by the correct entity.

The remoteness of far north South Australia and lack of resources to monitor the movement of people through the rangelands is a risk that requires a multifaceted approach. Active communication between the Pastoral Unit, National Parks and Wildlife Service, DIT and lessees is a useful tool to gauge road condition and weather events. This can help determine if sites of interests or PARs must be closed, and it also assists DIT in developing their Outback Unsealed Roads Grading Program.

Conclusion

Enabling sustainable access to the rangelands promotes the value of their societal contribution, and provides benefits to a range of industries, including pastoralism and agriculture, tourism and the environment. Lessees, visitors and the government need to be aware of the connection traditional owners have with the land and work collaboratively to ensure positive outcomes for the rangelands are realised. It is important for the future health and prosperity of the rangelands that stakeholders engage and work together to identify suitable accessibility solutions, especially as land use and demographic changes emerge in these areas.

Improved accessibility could be achieved through increased funding for maintenance and management of PARs, the identification of a broader outback roads network to be maintained by DIT, and through a collaborative approach with traditional owners, lessees and DEW to identify important cultural heritage sites for tourism promotion. This promotion could leverage funding to improve the condition and accessibility of the sites, including signs for safety, a maintenance program for road condition, and any other infrastructure to protect to integrity of the sites of interest, like fencing.

Risks and responsibility associated with rangeland access must be determined prior to any change in policy or decision making that increases or decreases accessibility. This will help clearly identify the rights and responsibilities of stakeholders who are accessing, visiting or using the rangelands. In doing so, proactive risk mitigation strategies can be deployed, allowing people to safely and sustainably enjoy the landscape.

The 'Drought Antidote' : An archaeology of artesian water management in NSW

Phelps, JEG[1]

[1] University of New England

Key words: Great Artesian Basin; Pastoralism; Drought Proofing; Water Security; Archaeology

Abstract

The Great Artesian Basin covers a vast area of inland Australia, enabling dependable water supply across the rangelands. In New South Wales artesian bores were introduced to benefit the pastoral industry, established by the Department of Public Works under the *Artesian Wells Act, 1897* and the *Water and Drainage Act, 1902*, hereafter referred to as the Artesian Scheme. However, the focus of research has been on current environmental concerns and the rehabilitation of artesian bores, with limited attention to historical water management strategies associated with the scheme. Remains of environmental modification from the Artesian Scheme are extensive throughout pastoral landscapes, although this archaeological record is delicate and disappearing with inadequate research conducted. This paper explores the origins of the scheme and considers localised variation, implementation, and operation through investigation of a case study: Sherwood Bore, near Rowena in north-west NSW. Drawing upon historical documentation, oral history and archaeological interpretation of remnant infrastructure, this research revealed the Artesian Scheme represented socio-economic development by supporting pastoral settlement opportunities and pastoral growth.

Introduction

A large portion of New South Wales (NSW) is arid to semi-arid rangelands which experience low, irregular rainfall. Limited permanent water sources restricted pastoral development until the initial drilling of artesian water in 1878 (Powell *et al.*, 2015) and subsequent confirmation of the large extent of the Great Artesian Basin (GAB) in 1892 (DPW, 1893). This vast groundwater basin provided a dependable water supply and enabled large-scale expansion of pastoralism (Murray, 2018). The GAB underlies 22% of Australia, spanning 25% of NSW (DPIE, 2023), and large areas of Queensland, South Australia, and the Northern Territory (Figure 1).

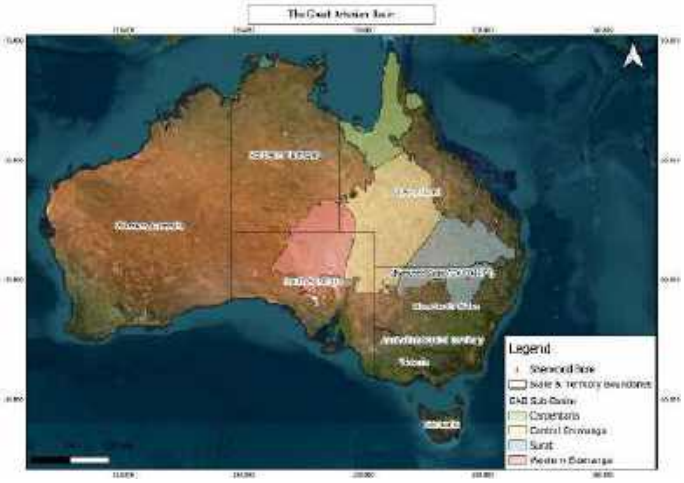

Figure 1: GAB Boundary (adapted from SEED layer "Water Sharing Plan – Groundwater Sources").

In the late nineteenth century economic, social, political, and environmental factors combined to encourage the initiation of one of the most ambitious modern schemes of deliberate environmental modification – the GAB Bore Scheme. From 1878, 8,000 bores were drilled across NSW as a means of providing permanent reliable water to landholders (DPIE, 2023), encouraging an expansion of European settlement into previously sparsely occupied areas, and significant growth of pastoral industries away from watercourses. In NSW, bores were sunk under the *Artesian Wells Act, 1897* and *Water and Drainage Act, 1902* for stock (sheep and cattle) and domestic applications, watering over 1,100,000ha (DPW, 1910, p. 9); hereafter referred to as the Artesian Scheme. These bores were governed by Bore Water Trusts, through elected Trustees, to oversee the maintenance through employing maintenance men, and operation of artesian water management (DPW, 1906). Associated water management infrastructure includes: *distribution tanks, divisors* (used to adjust the direction of flow), *bore-drains* (Figure 2a), and *water storage dams*. The Artesian Scheme represents unique rural engineering, governance, and employment in the context of a state development policy through expansion of the pastoral industry (DWE, 2009).

a)

b)

Figure 2: Sherwood Bore-drain (a) and Sherwood Bore (b), courtesy of D. Phelps, 2006.

The Artesian Scheme was successful in many of its aims, encouraging expanded pastoral settlement but also seeding its own demise. The early configuration of unregulated free-flowing bores led to significant problems with GAB water supply and the failure of much of the system. Since 1990 the *Cap and Pipe the Bores Program* (*CPBP*) has capped many bores and introduced reticulated systems of pipes, tanks, and troughs to reduce water loss through evaporation (DPIE, 2023). Consequently, in many areas the Artesian Scheme effectively finished more than 30 years ago, with prolonged deterioration, and operation is now almost out of living memory. Despite the significant impact on the development of European settlement in inland Australia and the pastoral industry (Godwin & L'Oste-Brown, 2012), the history at either a macro or micro scale is largely undocumented, with archaeological remains of the infrastructure vanishing or deteriorating.

This paper explores the history and archaeology of the Artesian Scheme in NSW. It aims to understand the archaeology of the scheme as an example of settler-induced anthropogenic change/environmental modification as a development strategy, as well as the industrial archaeology of the scheme and its operation. It will also examine regional implementation of the scheme, as well as micro-scale of a single bore's establishment, operation, and impacts upon adjacent properties, including the processes of maintenance of the bore and distribution system and its decline and modification over time. These aims are achieved through a case study focusing on Sherwood Bore (ID No. GW004471) (Figure 2b) which operated from 1907-2007, located near Rowena, NSW, on the property Glen Eden. This property has been owned and operated by the author's family since c.1902. Research explores historical documentation and generational oral history, combined with the archaeological record.

Methods

Investigation of the GAB was undertaken across multiple scales (state, regional, and local), which required an innovative combination of existing methodological approaches. Recognised methods were derived from previous studies and general literature to suitably combine interdisciplinary approaches to address the unique research topic. A multi-scalar approach was required to comprehensively understand such a large-scale management scheme, as there is interplay between levels where one informs the other, and which has not previously been undertaken for the historical period. Selected methods included the interpretation of historical sources, regional investigation, oral history, archaeological features, and artefact assemblages. The progression of the Artesian Scheme through macro and micro scales was achieved through the development of phases from the available evidence.

Results

Deliberation regarding the operation and implementation of such a large-scale water management scheme commenced in 1892 after a town bore was successfully sunk in Coonamble, which was previously considered outside the strata containing artesian water (DPW, 1893, p. 9). This success significantly increased the area of land with potential access to the GAB, prompting political discussion for future possibilities to supply permanent, reliable, water to regions periodically without water for the benefit of the pastoral industry. A subsequent design phase was characterised by experimentation and implementation of improved infrastructure and distribution approaches. By 1906 rapid implementation was underway to improve water security across an enormous pastoral landscape, "…which was formerly periodically denuded of stock by frequently-reoccurring droughts" (DPW, 1906, p. 5). In 1910, 48 Trust Bores were operational, supplying 1,102,695ha, with an additional 546,779ha proposed through future works (DPW, 1910, p. 9). Investigation of historical population change indicated no significant changes, suggesting the Artesian Scheme was intended to support economic growth, specifically for small pastoral enterprises to increase wool productivity. This also explains a concentration of Trusts within the semi-arid North-West, which had better potential to reach economic goals through reliable water supply, in comparison to the arid Western Division. The rapid geographic expansion of the large-scale Artesian Scheme was not reflected locally, and requires multi-scalar insight.

Localised progression represents the site-specific implementation of the Artesian Scheme through processes of construction and continuous maintenance to ensure dependable water supply. Archaeological survey introduced variation in management strategies and infrastructure, producing difficulties in comprehensively understanding the nature of this cultural landscape across numerous sites. Oral history revealed difficulties in the sinking of Sherwood Bore, and the effect individual agency from the maintenance men had on the archaeological record.

Discussion and Conclusion

Environmental archaeological studies of irrigation internationally have primarily focused on ancient management strategies (Shaw & Sutcliffe, 2001 & Konstantinov *et al.*, 2023), and advise a shift towards more sustainable modern practices. Guttman-Bond (2010) recommended sustainable ancient methods could be reintroduced, stating seven countries were successful, with further research underway. Reintroduction of knowledge was also proposed to combat aridification caused by climate change, noting methods may only be suitable across regions with similar climate conditions (Kaptijn, 2017). *Archaeology for Sustainable Agriculture* (2020, p. 420) suggested archaeology's strongest contributions were "…its ability to demonstrate that agricultural sustainability is historically contingent, and… its attention to outcomes, or completed cycles of agricultural development." This stressed the complexity and urgency for agriculture to improve sustainability, which would require on-going collaboration amongst diverse stakeholder groups (Fisher, 2020). This research highlights the ability for archaeology to enhance decision making, especially within water management and agricultural settings.

Large scale agriculture was also practiced in the Indus Valley in c.2600 BCE where an extensive network of canals was used for irrigation (Angelakis *et al.*, 2020). The use of bore-drain networks bares similarities in environmental modification to the Indus Valley, to supply water to extensive pastoralism, suggesting that the decision for distribution methods may have been influenced by previous approaches. However, unlike, ancient examples the Artesian Scheme was relatively short lived, spanning over 120 years, with initial implementation lasting only 19 years after discovery of water at Coonamble. The Artesian Scheme was also industrial, requiring less labour than the Indus Valley example, but rapidly causing dramatic change across a large landscape. Research into ancient water management indicates the longevity of environmental modification to improve water security for a variety of purposes. Research into management of the GAB could benefit understanding of ancient practices and can inform future approaches.

The use of artesian water was considered pivotal to pastoralism across arid and semi-arid regions in Queensland, NSW, and South Australia (Brake, 2020). Murray (2018) called for an archaeology of extensive pastoralism within the GAB, but did not outline a methodical approach, which this research has attempted to provide. Future directions could pursue variability through purposes of bores, landholder response, environmental variation, strategic differences in the Western Division, or a more detailed regional study through numerous case studies, especially of Florida Bore.

The Artesian Scheme was successful initially, substantially improving water security, especially during periodical droughts, but effectiveness varied, followed by early gradual decline. While historical water management was progressively phased out the Artesian Scheme endures, increasing the significance of understanding historical strategies to inform future decisions. Historical documents demonstrated the introduction of artesian water supply was intended to support pastoralism, enabling smaller enterprises to become viable – implemented following extensive pastoral sub-division. Interpretation of changing pastoral production in NSW revealed comparable stock populations, but improved resilience and industry response from periodical droughts, and supported increased productivity – this was reflected locally at Sherwood Bore through marginally improved stocking capabilities. This further suggests water security underpins production, while fodder insecurity and market dictate stocking responses. Review of regional population growth indicated no significant increase current to the introduction of artesian water, suggesting the Artesian Scheme was not intended to maximise population growth. Instead, the Artesian Scheme intended to maximise property number, settlement opportunities and economic growth through significantly improved water access and security enhancing wool productivity.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Fate of yak herding in the highlands of Mustang, Nepal: A case of Namu Bhrapse Rangeland

Sanjyal, S[1]; Joshi, S[2]; Gorkhali, N[1]; Dhakal, B[1]

[1]Nepal Agricultural Research Council, Lalitpur, Nepal; [2]International Center for Integrated Mountain Development, Lalitpur, Nepal

Key words: Livelihood; vegetation; tourism; climate change; employment.

Abstract

Rangelands are essential as they offer a range of ecosystem services that supports the livelihood of the people residing in the Himalayas. Yak herding is considered as one of the vital components of the rangeland ecosystem of Nepal. Yak farming tradition together with yak population are now facing an intensified decline mainly due to various reasons. Lack of palatable species, drying of water sources, lack of infrastructures and conflicts between local bodies and the government are some of the issues. While the earlier herders are getting old, it is difficult to entice the younger generations who are attracted towards lucrative business like agro tourism and cordyceps business that provides a great economic returns. As young people lack their interest in herding yaks, people from the neighbouring districts are paid to herd the yaks. Furthermore, climate change has led to worsen the scenario, with altered grazing pattern, lack of snowfall and rainfall and increasing temperature has depleted the vegetation quality and quantity in the rangelands. Unless there is an urgent intervention for sustainable management of rangelands from the government and local level, this culturally, economically, and ecologically important practice may disappear soon, leading to a serious repercussion on the communities and the environment they rely on. This study explains the scenario of rangeland of Mustang district namely Namu Bhrapsa Kharka which is a summer pastures for yak herding.

Introduction

Rangelands are a crucial part of Nepal's Himalayan ecosystem, covering 60% of the landscape and 22.6% of the country's total land area, including the mountains, hills, and Terai (Yi & Sharma, 2009; ICIMOD, 2012). These areas provide essential ecosystem services that support local livelihoods and environmental sustainability (ICIMOD, 2012). Mustang, located in the northern part of Nepal, is a dry region where yak herding, medicinal plant collection, and tourism are key sources of income for rural communities (Dong et al., 2009). Namu Bhrapse rangelands, at 3,700-3,800 meters above sea level, are a vital part of Mustang’s landscape, characterized by steep slopes and minimal precipitation (under 200 mm annually, mostly snow) (Pokharel, 2005). Agriculture and animal husbandry are the main economic activities, but productivity is limited by low rainfall, inadequate irrigation, and a short growing season (Chetri & Gurung, 2004). Despite their importance, Mustang's rangelands face anthropogenic pressures such as overgrazing, overexploitation of medicinal plants, and climate change impacts (Miller, 1996). Additionally, conflicts between human use and wildlife further stress the resources (Subedi et al., 2020). Effective rangeland management is crucial to improving livelihoods and income opportunities for herders. This study was conducted to examine the fates of the yak herding in the rangeland of Mustang to explore the socio-political aspects of sustainable rangeland resource management, contributing to the sustainability in Nepal's mountainous regions.

Methods

The study was conducted with five independent key informant interviews (KII) and two focus group discussions (FGDs) where yak herders, owners, *"Mukhiya"* (head of the village), head farmer and the technicians from the Municipality were interviewed to gather data on status of Namu Bhrapse rangeland in Gharapjhong Rural Municipality. Semi-structured questionnaires were used for the KII and FGD. Each FGDs consists of 10 yak herders and all were male. Additional data were collected through structured interviews, desk reviews, annual reports, workshop proceedings, and consultation at concerned municipalities and rangeland experts. Observations of Namu Bharapse rangeland included vegetation, yak herds, housing, and other infrastructure.

Results

During the FGD, eighty percent of the KII mentioned that yaks in Gharpojung Rural Municipality are basically reared for meat; yak meat and *"Sukuti*" (dried meat) is one of the key attractions to internal and external tourists to Mustang. In the past, yaks were used for meat only after their natural death, but now female yaks are culled in October as they age and lose their teeth, making them incapable of grazing or reproducing. Adult yaks are grazed in forests due to insufficient vegetation in the rangelands putting them at risk of snow leopard. Although the government offers 80% insurance for yak death due to accidents, disease, or predators, the protracted process often lead herders to prefer compensation through Annapurna Conservation Area Project (ACAP) said 92% of the herders. Eighty percent of the respondents stated that feeding is challenging in the rangeland because there is little vegetation and no additional supplement. Major grass species found in the Namu Bhrapse rangelands are *Cynanthus incanus, Herminium macrophylum, Bassecoia hookeri, Trogonella gracilis, Potentilla multifidi* etc, which are overgrazed. Recently, herders planted clover and rye grass, but the yaks overgrazed the lush greens, preventing their regrowth. Limited resources for reseeding led to the loss of germplasm. The government has installed some road tracks and water facilities, but they are insufficient for growing yak population. Herders, usually older males hired from other families' herd the yak of 2-4 families, are provided with food and salary for the year. However, the younger generation are lured towards international jobs/business, resulting in a shortage of herders, which is a serious challenge for yak rearing as reported by 95 percent of the respondents.

Discussion

The study gives valuable insights into the challenges of yak rearing in the Namu Bhrapse rangelands where the practice is closely tied to the economical, ecological, and cultural identity of this region but faces sustainability issue (Jing et al 2022). Yak rearing in Mustang is focussed on meat production however there is no legal provision for yak meat to boost tourism and local markets (Carter 2024). Insufficient vegetation and lack of support for provision of supplementary feeding complicate the practice (Kumagai et al. 2016). Grazing in forests exposes yaks to snow leopard predation, emphasizing the need for better predator management (du Chavoux 2020). Efforts to introduce grass species for restoration have failed due to overgrazing, indicating the need for better grazing management plans (Personal communication, 2024). Though the government has built roads and water facilities, they are insufficient for the growing yak population. High grazing taxes and limited rangeland support strain the economic viability of yak rearing. The reliance on older male herders and the younger generation's shift toward urban jobs presents a significant challenge to the practice (Banjade and Paudel 2008). To address these issues, government investment in sustainable systems, predator control, herder incentives, rangeland restoration and research on innovative practices and socio-economic solutions is essential.

Acknowledgement

Authors would like to thank ICIMOD and Dr. Yi Shaoliang for providing the resources and platform necessary to conduct this study. Authors are also thankful to Aaita Bahadur Thakali for arranging the herders for FGD and KII.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Agricultural developments on the rangelands of the Tibet Autonomous Region in China, with a special emphasis on the role of Tibetan women

Spiegel, NB[1]; Rose, CM[2]

[1] Department of Primary Industries, Queensland. PO Box 976, Charters Towers, Qld, Australia 4820 (former ACIAR Research Fellow); [2] Extension Agronomist (formally NSW DPI)

Key words: Tibetan agriculture; rural livelihoods; women in agriculture; selenium; adoption barriers

Abstract

Tibetan women play integral roles in agriculture on the rangelands of the high plateau of the Tibet Autonomous Region (TAR) in China. Agricultural development was the focus of ACIAR (Australian Centre for International Agricultural Research) funded projects in Tibet including capturing socioeconomic facets. Two projects that the authors worked on (2009-2012) provided the opportunity to explore firsthand livestock production systems in pastoral and crop-based areas of TAR. This paper aims to offer sociocultural insights, and to highlight the role of women in Tibet as enablers of change. For agricultural developments to proceed with greater success it will be important that women are included in changing practice.

Introduction

The Tibet Autonomous Region (TAR) spans 1.2 million km^2 (Tashi et al 2005). Livestock production is a predominant industry, where production systems (meat, milk and fibre) rely on long-established practices. Rapid changes brought about by increased industrialisation and urbanisation across TAR mean the traditional roles that Tibetan farmers and pastoralists once played are also changing. The Australian Centre for International Agricultural Research (ACIAR) has supported several projects in Tibet (e.g., Tashi et al. 2005; Rose 2011; Heath et al. 2012; Spiegel and Costa 2014) to aid the modernisation of agricultural practices so food and Tibetan livelihoods can be secured and poverty amongst Tibetan communities can be alleviated. A Tibetan researcher, the late Dr Nyima Tashi, was a strong advocate of agricultural developments in TAR, and actively established collaborative partnerships with ACIAR.

The following paper is based on the authors' combined firsthand research experiences during their time (2009 to 2012) working on agricultural development projects in TAR, written through the lens of an animal scientist (Spiegel) and an extension agronomist (Rose). Observational evidence, supported by project findings and literature, have allowed the authors to share their insights on pastoral and crop-based dairy systems in TAR, with a special emphasis on the role that women play in dairy production.

Background

TAR is made up of six prefectures and one municipal city of Lhasa situated at 3,656 m asl. Across the prefectures there are 74 counties, almost 900 townships and over 7,000 villages (Tashi et al. 2005). ACIAR funded research on the mineral nutritional status of Tibetan livestock and integrated crop and dairy systems. The former project identified many mineral insufficiencies and deficiencies (Tashi et al. 2005) and confirmed some alarmingly low, location-dependant, selenium levels in livestock (Spiegel et al. 2011). Two locations of particular interest included one crop-based township (Duopozhang) and one pastoral county (Jiali).

Selenium deficiency in livestock can result in reproductive disorders, but in humans, debilitating multifactorial diseases can occur, such as cardiomyopathy Keshan disease and osteoarthropathy Kashin-Beck disease. Both diseases are known to China, especially within areas of selenium deficient soil spanning from the northeast of China to the southwest to include parts of TAR (Yang et al. 2010; Yao et al. 2011).

Research efforts focussed on improving the nutritional status of Tibetan livestock involved authors spending extended periods in TAR: 5 months (Spiegel) and 3 to 4 weeks (Rose) each year from 2009 to 2012. Mineral surveys and mineral response trials were conducted across counties and production systems (see Spiegel and Costa 2014), and economic (Waldron et al. 2016) and attitudinal surveys (Rose 2011) conducted in the cropping zone of TAR. For the latter, adaptive research surveys, used to assess farm adoption opportunities and barriers, were conducted orally with farmers in Tibetan to avoid literacy issues and poor understanding of Mandarin. Impressions on the Chinese/Tibetan researchers' attitudes were made during presentations to scientific meetings and general discussions during data gathering.

The focus of this paper is on the two locations of Duopozhang and Jiali, representing respectively a crop-based and a pastoral-based livestock production system in TAR at risk from severe mineral deficiency.

Crop-based livestock system: pathways for agronomic practice change

This zone is characterised by traditional farming of intensive cropping and smallholder livestock production on valley floors (Fig. 1) and lower hill slopes with the average farm size of 0.8 ha (Heath et al. 2012) and altitudes ranging between 3,600 to 4,000 m asl. The township of Duopozhang in Naidong County (Shannan Prefecture) was especially of interest to the minerals project (Spiegel and Costa 2014) owing to the very low mineral selenium levels identified in dairy cattle – lower than any international previously published results – and severely low dietary energy and protein intakes of livestock, as seen by poor body condition. Research efforts were consequently concentrated here (e.g., see Waldron et al. 2016) and attitudinal surveys conducted with farmers in 2011 (see Rose 2011 & 2013).

During the authors' time spent in Duopozhang (starting in 2009), rapid changes were taking place. Investment in the expansion of this township by The Peoples Republic of China (supported by a range of International aid projects) meant roads were being developed, additional livestock (e.g., Boer goats and pigs) and new cattle genetics introduced, access and availability of water to households and for crop irrigation was being improved, Lucerne was being planted, methane digesters to supply energy for heating were being trialled, and extension efforts by local officials were starting. Research efforts by local organisations (TAAAS: Tibetan Academy of Agriculture and Animal Husbandry Sciences and the Tibet Poverty Alleviation Office), and international collaboration (TAAAS and ACIAR) were operating simultaneously for maximum impact and allowing for a test site that, if successful, could be used as a model for other crop-based villages in TAR.

During field research, we observed Tibetan sociocultural attributes, behaviours and traditions that underpinned, and were unique to, the production systems in question.

Firstly, it was apparent that Tibetan households were not only dependent on their livestock, but that their daily work, especially of women, largely involved managing livestock. Animals were kept in close quarters and fed with whatever was available, including household kitchen scraps. The dung from cattle was collected, dried and later used as fuel in the household for warming and cooking. Daily routines of Tibetan women also included feeding, watering and milking their cattle by hand twice daily, managing the calves to restrict suckling, letting cattle out of the house yard to graze available pasture (e.g., on the grazing common or tethered in cropping fields to graze weeds or crop residues), and collecting forage for their cattle (cut and carry practices of woody browse species). Secondly, the milk collected was churned by hand to make butter, the highly valued dairy product used to make Tibetan tea (traditional salty butter tea), with some butter spared for butter lamps in households for religious reasons. The use of butter as a form of topical cream to treat cracked teats in milking cattle was also disclosed by some of the households.

In terms of production, local dairy cows (as locally bred) are of small stature and low milk production. Traditional feeding includes very limited grazing, feeding of weeds, and in winter the use of straw as arable land is used for human consumption crops. As a result, animals have poor nutritional status, including low energy and protein intakes and restricted water intakes. Improving the mineral nutritional status of their livestock would have the benefit of boosting trace elements (such as selenium) in the human food chain. However, without correcting for under-nutrition, the full benefits of mineral supplementation and production responses would not be seen. Thus, overcoming protein and energy deficiencies in dairy cattle was priority. Adopting a focus on agronomic practices and cropping was required. As such, the attitudinal survey (Rose 2011 & 2013) sought to understand motivations for farming decisions and barriers to adoption of practice change such as practices of growing forage crops, double cropping, and supplementary feeding of stock.

The main motivation for increasing production was for a better life, with buying equipment a distant second. Lack of capital was a barrier to trying new ideas on farm, so opportunities to work off farm were considered important to provide the necessary cash flow. A major contradiction though, is that off farm work creates major labour shortages at peak times like harvest. Heath et al. (2012) discuss that strategies such as double cropping with fodder crops have the potential to increase production yet increase labour pressure at peak times. The survey also revealed a general reluctance of the older generation farmers to encourage succession to their younger generation. Observations of the women surveyed was the women did not identify themselves as the primary decision maker in farming decisions.

Delving into the adoption of improved production techniques, the farmers were willing if the practice was able to be done (e.g., new barley varieties / oats / vetch seed available), the up-front costs were not beyond their cash flow, and that the practice worked on their farms. While most projects supplied the early inputs to avoid the cash flow issues, the authors saw that while strategies such as growing maize were successful in the research phase, farmers said they were unlikely to adopt in the long term due to cost barriers. On the other hand, oats had survived beyond the research phase, as seed sales made it an economic option. Some resistance to lucerne had been overcome by the value of selling forage in the towns. Barriers to freely available water for dairy cows include access to flowing water, and the increased runniness of dung being associated with illness in the livestock and increased difficulty in fuel preparation.

Survey questions showed that little extension was done at their villages. Though farm schools were run, Chinese/Tibetan researchers lamented that farmers had to be paid to attend, and farmers felt that the schools were too hard to get to. While fertiliser and insecticides were widely used, there was little understanding of which ones to use or why they did or did not work, or even what the pests were. Herbicides were not popular as weeds are a fodder source for stock.

Pastoral system: settlement and flow-on effects

This zone is characterised by treeless rangeland pasture, inhabited by Tibetan sheep, goats and yak and Tibetan nomads/herders (Fig. 1). Pastoral counties investigated by Spiegel and Costa (2014) included the yak and sheep production counties of Damxiong (4,200 m asl) and Naqu (4,500 m asl) and the yak production county of Jiali (4,500 m asl). For the latter, very low mineral selenium levels were detected (Spiegel et al. 2011).

The restructuring of TAR into production zones (Tashi et al. 2005) and the settlement of people into townships and villages has allowed for the provision of centralised services throughout TAR such as health care and schools, and the development of new housing. However, the restriction of movement of nomads as a result has led to unwanted consequences, such as the concentrated grazing pressure and increased parasitic infection in livestock grazing contaminated pasture observed by the minerals research project during their investigations, as well as degradation of the rangelands seen across different pastoral areas in TAR. Animal diseases and animal husbandry issues have negative flow-on effects for animal production and each household's ability to maximise food production. Although, having centralised services mean animal husbandry extension can be easily established within a county to service the local villages. The construction of a veterinary branch in Jiali County (Naqu Prefecture) for instance was taking place during the authors' time in TAR and could have an invaluable future role to play in disease control and prevention, stocking rate management and in extension and education. Two prevalent diseases affecting Jiali yak production observed by the minerals project included Warbles (Subcutaneous myiasis; caused by warble fly infestation) and brain parasites (Coenurosis; caused by the intermediate stage of the tapeworm *Taenia multiceps*) (Spiegel and Costa 2014).

Despite the rapid changes and modernisation that has been occurring in TAR, we observed traditional ways of life, such as Tibetan pastoralists still living in summer and winter tents. Pastoralists manage yaks for both milk and meat. Nomadic women churn yak milk into butter, an important part of the traditional diet. Other production includes the making of hard cheese, yogurt, yak blood sausages and dried yak meat. Some modern features observed included motorbikes, mobile phones, solar panels and electric appliances such as kitchen blenders. The collection of yak dung for fuel was still apparent at the time and no alternative heating or power for cooking was observed. The upkeep of a stupa (Buddhist shrine) in the township also meant locals could still openly practice religion and meditation, such as carrying out daily circumambulation (kora).

The practice of caterpillar fungus harvesting was encountered. This fungus (*Ophiocordyceps sinensis*), a unique medicinal fungus, is physically dug out and removed from the rangelands soil for trade. What was apparent through translated conversations was that nomadic households could boost annual earnings through harvesting and trading the highly priced *O. sinensis*. Some family members were carrying out annual spring harvesting and therefore spending extended periods occupied by this seasonal work activity rather than by daily livestock activities. The opposing effects for the household are apparent: good for cash flow, but reduced household capacity to tend to livestock. Wang et al (2018) identified other mixed flow on effects, such as low school attendance rates, possibly due to the lack of perceived benefits from education. In addition, there is concern over the overexploitation of *O. sinensis* contributing to the degradation of alpine and sub-alpine pastures (e.g., Hopping et al. 2018).

From extensive time spent in TAR, we observed pastoral women in contemporary Tibet fostering a strong connection and identity to their culture, including traditional dress worn in their homes, providing traditional hospitality, and conducting daily animal husbandry practices using traditional methods. During the field sampling of livestock, women were always present and playing an active role in sample collection. Dairy related tasks such as milking, yogurt and butter production were predominantly done by women. Women were handling their animals daily and a strong bond between handler and animal was evident. For instance, during jugular blood collections of yaks for mineral sampling, any yak that was not tolerating being restrained was quickly quietened and soothed by the presence and touch of their female herder. Animal handling techniques were also passed down to the next generation, with children exposed to animal husbandry or actively involved, for example decorative bags containing salt were carried by older children to lure yaks.

Discussion

Our observations suggest that Tibetan women play pivotal roles in shing-lay (Tibetan for agriculture) and are well placed as being integral to decision making for dairy production on the rangelands in TAR. Our experience from household visits and survey, showed most women do not identify themselves as the primary decision maker; but that may indicate women are more inclusive, rather than that men dominate the farming decisions. The trend towards reliance on off farm income, increasing the ratio of women to men managing the land, will only increase the role of women on the land. It is therefore pivotal that extension of agricultural research is tailored for both genders. For instance, participatory action learning for women would ideally focus on how production-related changes can interact with the household. Training at the village would be desirable, as women will be less likely to attend if training takes them away from their daily work and children. For men, the focus might be on production and could include training following adult learning principles, away from the village. Changing the perception of the low value of agriculture, to one of a valued profession, as well as increasing production from subsistence to trading, could help reverse the trend of discouraging the younger generation from farming. Part of this is the training of Tibetan farmers and herders to enable them to make informed decisions on inputs and outputs, rather than the top-down supply of information and inputs. Surveys identified, for instance, farmers applying nitrogen-based fertiliser to lucerne, as that was what they were supplied, and a very low knowledge of pests and diseases of both plants and animals. Research would also benefit from the two-way flow of information.

Other changes in a modernising economy may also have a major impact. For instance, in one village visited, methane digesters supplied energy for heating, making the collecting of dung for fuel redundant, and leading to dung being returned to the fields. In terms of optimising milk and meat production, breeding programs and the adoption of yak crosses and larger framed cattle in TAR (e.g., Holstein local cow crosses) run the risk of many adverse consequences, such as increased dystocia, exacerbation of protein and energy deficits, reduced butter fat content of milk, as well as loss of well-adapted native breeds and ecotypes.

Female Tibetan agricultural researchers also have a role to play to assist and promote agricultural developments, however they appear to experience dislocation from their roots due to extended education in ‘mainland’ China. Despite this, the female researchers assigned to survey work were willing to engage in the extension concept and showed empathy with the farmers. From the authors own observations during their time in Tibet, research was the primary focus and endeavour of many, with extension considered to be an early career job with low status. On a study tour to Australia, Tibetan / Chinese colleagues were amazed to meet highly respected extension specialists. This is a paradigm shift that research aid projects could aim to address.

The attitudinal survey work demonstrated the importance of embedding a strong social and extension component into research and development projects. For instance, the unexpected findings of Tibetan farmers using butter on cracked teats of dairy cattle or using nitrogen fertiliser on legumes offers a segway to exploring different methods for adoption to boost trace elements in the human food chain. For example, improved daily management of dairy cattle/yak udders could simply include an iodine-based (‘Iodophor’) teat dip disinfectant. The udder can absorb the iodine. For the application of fertilisers on crops, the option to use selenium fortified fertilisers on both fodder and cereal crops might be worth exploring to boost selenium levels in both animals and humans (G. Lyons, pers. comm.). All research and extension should, however, consider the risk of unintended negative consequences and remain flexible to alter direction.

The paper explored two different livestock production systems operating in TAR. The opportunity for future work to explore potential linkages and trade options between the two systems deserves research attention. With the potential to test new feeding systems and animal husbandry practices in the cropping zone of Tibet and to test and develop disease control in pastoral areas of Tibet. For example, there could be a natural exchange of knowledge and supply of feed concentrates across counties to bolster developments in agriculture on the Tibetan rangelands. Climate change and reduced isolation also leads to a need for further research as growing seasons lengthen and more pests and diseases emerge, and will change accepted management practices.

Acknowledgements
The authors gratefully acknowledge ACIAR and AusAID for supporting agricultural research projects in TAR. We thank staff from TAAAS, Tibet Livestock Research Institute & local Counties, the Tibetan Herders &

Farmers. Expertise in livestock mineral nutrition and assay by Geoff Judson, Nick Costa as well as staff from the Chinese Academy of Agricultural Sciences in Beijing is kindly acknowledged. Animal ethics approval was obtained from Murdoch University, Murdoch WA (Permit R2246/09).

We also acknowledge and give thanks to the Late Dr Nyima Tashi (1966-2020), born to a farming family in Tibet, Shannan Prefecture and a progressive scholar and Tibet's chief scientist of highland barley crop breeding and the former head of the Tibet Academy of Agricultural and Animal Husbandry Sciences. He will be remembered as a champion of Tibet food security.

Key words: Knowledge Functions, Pastoral Traditional Knowledge, Pastoralism, Traditional Ecological Knowledge

Abstract
Pastoral traditional knowledge is gaining recognition for its adaptability and role in enhancing the resilience of pastoral communities. To deepen our understanding of how this knowledge system demonstrates adaptive characteristics, we employ a functional lens to examine its dynamic nature in this systematic review. Our analysis, based on insights from 152 case studies worldwide, shows that this knowledge system has various domains and serves diverse functions, including ecological, economic, and socio-cultural functions, with further subfunctions. Ecologically, it primarily boosts climate resilience and adaptation; economically, it supports herd health and productivity; and socio-culturally, it preserves cultural identities and heritage. Furthermore, our findings highlight that each knowledge domain shows multifunctional characteristic. Our analysis also helps identify common functions across eight knowledge domains, each contributing to areas like sustainable resource management and climate adaptation, though to varying degrees.

Introduction
Pastoralist communities globally are confronting a myriad of challenges. Climate change is disrupting their traditional lifestyles through unpredictable weather, intensified droughts, land degradation, and poorer pasture quality (Ahmed et al. 2023). Socio-economic factors such as market dynamics and resource extraction are straining their adaptability (Galvin 2009). Additionally, land ownership policies and conflicts limit access to essential resources, compounding these pressures and threatening both the ecological balance and the cultural continuity of pastoral societies (Xie and Li 2012).

Despite these challenges, pastoral communities persistently employ and renew their traditional knowledge, continually learning from and adapting to changing environmental conditions and socio-economic landscapes. To dig deeper into how pastoral traditional knowledge (PTK) helps pastoralists adapt and thrive amid changing environmental and socio-economic pressures, we decided to apply a functional lens in this study. The function of knowledge, within this context, refers to the deliberate use of knowledge to achieve specific objectives as well as the actual impacts or outcomes of the knowledge. Specifically, we review the literature 1) to document the domains of PTK, 2) to explore the diversity of functions PTK serves in the lives of pastoralists, 3) to investigate whether a single PTK domain can serve multiple functions, and 4) to examine whether different PTK domains share common functions.

Methods

Our review used primary sources from peer-reviewed literature on PTK from the Web of Science and Scopus. The search string used was TS= ((traditional OR Indigenous OR local OR past OR old OR folk OR aborigin) AND (pastoral* OR nomad* OR herd* OR shepherd OR flock) AND (ecology* OR environment* OR rangeland OR grassland) AND (knowledge* OR practice* OR strategy*)) AND TS= (adapt* OR cop*). The initial search yielded 1076 documents (WoS = 432; Scopus = 644). After removing overlapping documents based on DOI, title, and abstract comparisons (n=318), we thoroughly screened 758 publications for relevance to our review, focusing on title, abstract, and methods. We included only peer-reviewed studies that provided empirical evidence of PTK and had a clear focus on PTK. Studies that only partially addressed PTK were included if the relevant section to PTK provided detailed insights. Publications were restricted to those available in English or Chinese. Ultimately, 149 papers met our criteria and were included in the review.

To investigate diverse domains and functions of PTK, we conducted qualitative thematic analysis and coded the verbatim statements referring to PTK, its applications and its outcomes in Nvivo. Additionally, we quantitatively assessed the distribution of the coded functions among different domains using the R program, specifically 'dplyr' for descriptive analysis and 'ggplot2' for data visualization. Using 'dplyr', we evaluated the distribution of different functions across various PTK domains and analyzed how these knowledge domains contribute to various functions by calculating the percentage distribution within each sub-functional group.

Results

Domains of PTK

Results from our analysis expand upon the initial framework proposed by Sharifian et al. (2022), who identified five key knowledge domains: livestock, forage/plant, landscape, climate/weather, and social-cultural knowledge by adding two new domains to this classification: herd mobility practice and herd diversification practice. The distribution of different knowledge domains across case studies shows a significant variation. More than half of the case studies (84, 55%) reported only one or two knowledge domains, while 39% (59 cases) documented three to four domains. Notably, only 9 cases (6%) documented a range of five to six knowledge domains. Among the knowledge domains documented, herd mobility is a practice most frequently reported, identified in 82% of cases (124 cases) across all climate zones. Climate and weather-related knowledge is the second highest cited knowledge domain, reported in 41% of the cases (n = 63). Knowledge domains relatively less often mentioned in the literature include landscape-related knowledge and herd diversification practice. Landscape-related knowledge was found in 33 cases (22%). Pastoralists routinely observe and learn about their surroundings while herding.

Diverse functions of PTK

Our analysis suggests that PTK covers different ecological, economic, and social-cultural functions in pastoral systems. Within the dataset analyzed, a total of 252 citations are applied to support ecological functions. PTK ecological functions include various subfunctions such as monitoring ecosystem health, preventing unsustainable resource use, predicting weather and climate variations, and maintaining biological diversity in the ecosystem. Upon examining the distribution of these citations among different knowledge domains, it is apparent that the domains of herd mobility practice (78 citations) and climate/weather-related knowledge (55citations) are prominently associated with ecological functions.

PTK's economic functions refer to PTK's role in enhancing the efficiency and sustainability of pastoralists' livelihoods. We identified three different subfunctions in this group: utilizing limited resources effectively, mitigating the impacts of natural disasters, and improving livestock productivity and health. Among all the recorded citations, there are 139 of them which play economic functions among pastoral communities. The domain of herd mobility (43%, 59 citations) emerges as the most prominent within this economic category. Although forage/plant-related knowledge is not prominently featured for its ecological function, this knowledge domain made up 18% (26 citations) of PTK economic functions. Livestock-related knowledge accounts for 11% (16 citations) of the economic functional group.

The social-cultural functions of PTK contribute to the maintenance of pastoral communities' cultural integrity and social structures. This functional characteristic stresses PTK's role in preserving traditional culture but also in enhancing the social bond of the community and promoting cooperation. Among the recorded citations, 59 citations are documented as fulfilling social-cultural functions. Social-cultural functions draw in social-cultural knowledge, which forms nearly half of this functional category (48%, 29 citations). However, it is interesting to note that livestock-related knowledge, accounting for 11% of all social-cultural functions, and landscape-related knowledge, representing 10%, also contribute meaningfully to the social-cultural fabric.

We further analyzed the data to better understand the weight of different subfunctions within the three main functions. The ecological functions of PTK stands out as the most common, with over half (58%) of the recorded subfunctions addressing four ecological functions: ecosystem monitoring, sustainable resource use, climate adaptation and resilience, and biodiversity conservation. Within ecological functions, climate adaptation and resilience is the most often cited subfunction, comprising 35% of all recorded citations. The subfunction of sustainable resource management represents 17% of the citations. Within economic functions, enhancing livestock productivity (14%) and livelihood support (12%) are two subfunctions most often cited. Overall, the social-cultural functions of PTK are the less often cited. Within those, cultural preservation (7%) is emphasized to a larger extent than some ecological and economic functions, including ecosystem monitoring and risk management.

Multifunctional characteristic of PTK domains

Our results also reveal that most domains are connected to distinct functions. For instance, social-cultural knowledge covers ten types of subfunctions, ranging from climate adaptation and resilience to social cohesion and community governance. Livestock-related knowledge, which one might expect to predominantly impact areas directly related to herd management, such as productivity, in fact, shows a diverse range of functions.

Common functions across PTK domains

In our comprehensive analysis of PTK, a pattern of common functions among various knowledge domains emerged. all the knowledge domains examined collectively contribute to sustainable resource management, and climate adaptation and resilience functions. In terms of knowledge domains contributing to economic subfunctions, all the knowledge domains were found to jointly contribute to improving livestock productivity. Furthermore, herd diversification and herd mobility practices were often intertwined in addressing risk management. Culturally, almost all the knowledge domains contributed to the preservation of cultural identity and heritage. Although social-cultural knowledge played a dominant function in improving social cohesion and community governance, some case studies reported that herd mobility could serve the same purpose.

Discussion

Our study reveals significant imbalances in the focus of existing case studies regarding knowledge domains. The fundamental knowledge of pastoralism globally, such as livestock-related (10% of the cases), forage/plant, and landscape-related knowledge are significantly underrepresented. Additionally, we found that more than half of the case studies (55%) investigated only one or two knowledge domains. This underrepresentation is problematic because it fails to capture the full complexity and interconnectedness of the pastoral knowledge system. Global research on traditional pastoral knowledge shows that pastoralists across diverse regions use a complex and common set of principles, including forage/plant, landscape, and livestock knowledge to manage resources efficiently and sustain their livelihoods (Sharifian et al. 2023). By focusing narrowly on certain aspects, research risks oversimplifying the holistic strategies that pastoralists employ. Pastoralists do not view these domains in isolation; rather, they integrate multiple domains to adapt to environmental uncertainties and ensure the sustainability of their resources. Thus, we argue that this narrow focus and fragmented approach risks presenting an incomplete or even distorted understanding of PTK. It fails to capture the holistic strategies pastoralists use to manage uncertainty and ensure the sustainability of their resources.

Moving from the specific domains of PTK to its broader implications, PTK exhibits diverse functions, playing ecological, economic, and socio-cultural roles. In our database, the most common ecological subfunction of

PTK is climate adaptation and resilience, which appears more frequently than the sum of the rest of the ecological subfunctions. This prominence likely stems from pastoralists' direct experience with climate variability, such as droughts, floods, and shifting seasonal patterns, underscoring their adeptness at navigating and mitigating the adverse effects of weather variability, and potentially of climate change. Regarding the economic aspect, PTK is mainly mentioned for enhancing herd productivity, and livelihood support and resource optimization. The findings show that forage/plant-related knowledge and mobility practice are the core for maintaining herd health and productivity. This aligns with the findings of Launchbaugh (2020), who highlighted that livestock could benefit from mobile grazing behavior by taking a variety of forage with different nutritional qualities. In terms of social-cultural functions, we found that livestock-related knowledge and landscape-related knowledge play significant roles in preserving the cultural identity and heritage of the pastoral communities. The landscapes that pastoralists inhabit and manage are imbued with cultural significance. Managing and preserving these landscapes, therefore, becomes an act of cultural heritage conservation. In certain communities, specific practices in landscape management, like controlled burning, are important parts of their culture (Fernández-Giménez 2015).

Building on the understanding of these varied subfunctions, our findings suggest that each domain of PTK serves multiple ecologic, economic, and socio-cultural functions. The significance of multifunctional characteristic within the knowledge system is profound. It enhances community stability by equipping them with a diverse set of strategies to deal with uncertainties and ensures that knowledge itself remains pertinent and flexible, capable of adjusting to evolving challenges. As some case studies show, even when a community is faced with constraints such as privatization, mobility adapts to fulfill other important functions, such as land preservation. This gives reason to believe that the multifunctional characteristic of traditional knowledge systems contributes to their continued relevance and transmission. Therefore, future studies could examine this relation more directly. Additionally, there is a significant opportunity for future studies to explore how these functions evolve and adapt over time, particularly whether knowledge domains develop new functions in response to environmental and social changes.

Expanding on the finding of multifunctional characteristic of each domain, another finding that deserves attention is the substantial common functions present across knowledge domains. The idea that communities utilize alternative knowledge to achieve similar outcomes due to various challenges is discussed in the existing literature. For instance, Gauer et al. (2021) explore how Indigenous communities adapt their knowledge in response to environmental changes, employing alternative strategies when certain knowledge becomes impractical or ineffective. Drawing on these findings, we propose that future studies could interpret this interplay and synergy as a mode of strengthening traditional knowledge systems. We hypothesize that the common functions identified across different PTK domains allow pastoral communities to approach challenges such as climate change from various angles, thereby increasing the likelihood of finding a more effective solution.

Given the diverse range and complex interplay of ecological, economic, and socio-cultural functions within PTK, there is a need for adopting an interdisciplinary approach. By incorporating perspectives from various fields, future studies can achieve a more holistic understanding of traditional knowledge systems and their functions. Additionally, there is a need for future studies to involve and collaborate directly with local communities. In this way, researchers can ensure that their work captures the full depth and interconnectedness of PTK while respecting and valuing the perspectives and lived experiences of these communities.

Abstract

Pastoralists are among the most vulnerable groups to climate change and variability, as they depend on bioclimatic conditions for livestock forage biodiversity and production. In the complex socio-ecological system of the mountainous area of Montesinho Natural Park (north-east Portugal, Western Europe), traditional pastoralists are impacted by climate change in their rangelands (e.g. average monthly temperature increase, shifts in precipitation patterns) (Castro et al. 2021; Oliveira 2023).

To understand the adaptive responses of local pastoralists to environmental change, this interdisciplinary research applied a three-step method. Firstly, we performed walking ethnographies with shepherds for over two years and used dialogues and observations to identify perceptions and local adaptations. Secondly, adaptive practices from other pastoral groups that could be viable in the study area were identified from the literature. And thirdly, co-participatory consultation workshops with pastoralists and representatives of local and national entities were developed to discuss and assess the adaptive measures for its practicality and sustainability.

Shifts in precipitation patterns, drought and higher temperatures in the winter were identified as climate changes by local pastoralists, and several adaptive practices for water provision and conservation, additional fodder supply and livestock thermal comfort were listed by all local stakeholders involved in the project, as feasible solutions to overcome regional ecosystem shocks and trends.

Local knowledge and climate perceptions were important for the documentation of adaptations at the rangeland level. This integrative approach, which resulted in a good practices guide, promotes practitioners and decision-makers to identify and discuss measures that will contribute to the resilience of traditional mountain pastoralism in the protected area of Montesinho and similar agro-pastoral systems.

Introduction

Pastoralism is an ancient practice that requires flexibility and adaptability to respond to social, political and ecological landscape changes. Up to the 20th century, this practice was economically important in northern Mediterranean mountains and remains so in the Natural Park of Montesinho (PNM) in north-east Portugal, Western Europe. Here, traditional pastoralism contributes to landscape management, provides ecosystem services, is a source of animal protein in local diets, and represents cultural identity (Castro et al. 2021). Despite a significant reduction in the total number of animals and shepherds using the territory due to these historical changes, pastoralism remains an important activity in PNM. As with mountain pastoralists elsewhere, however, we are yet to understand how these groups will overcome contemporary climate challenges, or the social and ecological impacts of this practice collapsing.

Future north Mediterranean landscape projections include increased aridification and desertification as a result of climate change and current exploitation rates (Lazarev 2022). In the PNM region, recent investigations on climatic normals over the past 70 years, reveal reduced spring and increased autumn rainfall, alongside consistently increasing annual average temperatures (Oliveira 2023). Such events can deplete drinking water resources and induce heat stress in animals and plants, degrading animal health and decreasing palatable biomass, culminating in reduced livestock productivity and increased livelihoods risks (Kgosikoma et al. 2018).

Elucidating pastoralists climate change perceptions, significant impacts on activities and adaptive responses is therefore urgent. In such socio-ecological systems, as complex as PNM, an interdisciplinary approach integrating anthropological, ecological and climate knowledge is crucial for pastoralism resilience.

In this study we aim to (i) obtain insights into regional climate change perceptions amongst shepherds, (ii) identify the feasibility of climate adaptations to strengthen livelihood resilience, and (iii) provide technical oversight regarding adaptations suitability and sustainability. Project outputs will include a regional good practices guide.

Methods

The Natural Park of Montesinho (PNM) was established in 1979. The mountainous area (approximately 74,000 ha) has an elevation range between 445 and 1,487 m, average annual rainfall between 1262 and 806 mm, and average annual temperature range of 8.5 to 12.5°C (INMG 1991). The park is rich in plant and animal biodiversity mainly due to its climate, geology, and the transboundary river system with the neighbouring country, Spain. Just over 4500 people live within the park and livelihoods include both rural and non-rural activities. Pastoralism is a practice performed by fewer people than in the past, but the park still sustains herds with totals of 20,001 sheep and 687 goats across 35,296 ha of shrublands, woodlands, and cultivated areas. The low number of residents, particularly shepherds, reflects ongoing social and economic change.

To firstly identify climate change perceptions and other socio-economic-political changes affecting pastoralism in PNM, seasonal walks were undertaken between 2022 and 2023 with local sheep and goat herders. An ethnographical approach using conversations and observations yielded data, which was analysed qualitatively to identify perceptions and knowledge on specific themes: transformations in land use and pastoral activities (historical and contemporary), political and economic challenges, agrosilvopastoral resilience, pastoralists perceptions on climate change and adaptive responses. The list of adaptations identified was complemented with adaptations applied in other mountain regions globally, which could be viable under the PNM ecological, political and social conditions.

These adaptations were reviewed and discussed in co-participatory consultations held with regional pastoralists in two villages within the grazing territory of the project shepherds. The sessions comprised of presentation and discussion of project results grouped into (i) pastoralism in the past and in the present, (ii) climate change perceptions, and (iii) how to address the future as a pastoralist. The first and second parts were presented using photographs portraying life in the past and present and a summary of the descriptions and perceptions of pastoralism and climate changes provided during the ethnographic walks, which instigated open discussions among participants. The third part comprised of a comparison between two photographs depicting a current productive landscape and a future drier scenario. The adaptive responses identified during the walking ethnography and the literature review were presented to the participants in the form of smaller photographs, which were either selected or discarded according to its practicality, efficiency and applicability in the PNM, and prioritised based on the pastoralists needs. A final workshop involving local stakeholders engaged with the agrosilvopastoral system of the park (members of national associations of local breeds and governmental agencies) followed a similar structure. The participants were invited to contribute with their technical knowledge on discussions about the executability and enforcement requirements of each adaptation. Every person involved in this study was individually invited to participate, and informed about the research aims, outputs, and their rights to withdraw at any point.

Though this study aimed to present how PNM pastoralists are adapting to climate change, our work addressed a limited number of male only participants with a narrow age spectrum (50-69 years). Additionally, across the years, different researchers conducted the ethnographic walks which could have contributed to some bias as we did not follow an interview script. When conducting the co-participatory consultations, thinking of a future scenario with drastic water shortage and warmer periods was not always an easy task for some participants. Moreover, we believe some discussions among stakeholders were guided by their professional link to a regional/national entity.

Results

Walking ethnography yielded important insights on temporal changes in work organisation, dynamic agrosilvopastoral system resilience, and climate change perceptions. Furthermore, coping mechanisms were identified for the changing conditions pastoralists currently face. Climate change perceptions, suggest that seasons are less well defined compared to the past, winters are warmer, and there is less water in the soil (e.g. many springs and small streams have dried or have little water). Pastoralists further reported that rainfall no longer follows monthly patterns, frost and thunderstorms occur at unexpected times of the year, and snowfall frequency and quantity are lower. All these changes are believed to impact fodder productivity and drive higher resource and materials costs.

Adaptations implemented by PNM pastoralists and in other regions were reviewed by all parties (shepherds and stakeholders) involved in this traditional practice during the co-participatory consultations. The two consultations with local pastoralists resulted in the selection of 14 and 11 relevant adaptations, a difference most likely due to the edaphoclimatic characteristics of the west and east regions of the park where the shepherds graze their herds. We grouped the selected adaptations into three types: adaptations in the grazing territory, to the grazing of animals, and to the livestock production. Many of the response mechanisms were directed at providing water and forage for the animals, valuing and diversifying livestock products (e.g. added value product; production of cheese), and improving animal health. Priority among pastoralists was given to adaptations to be implemented by regional and national entities rather than by the shepherds themselves, probably due to the grazing territory being within a protected area with strong conservation enforcement and laws.

Discussion [Conclusions/Implications]

Pastoralists perspectives on precipitation and temperature variation, and other climatic hazards (e.g. lack of snow), reflect the changes taking place in PNM inferred from climatic data (Oliveira 2023). Moreover, they highlight the negative impact such events have mainly on water availability and crop productivity in PNM. As a response, all shepherds, regardless of their territories characteristics, apply coping mechanism frequently observed in other rangelands across the globe (Herrero et al, 2016): place water points in the territory, grow crops that are more drought resistant to feed animals in face of pasture shortage, adjust shepherding routes. Adaptations priority, however, appear to respond to the edaphoclimatic conditions of the grazing grounds. Planting trees and conserving pastures were top adaptations for pastoralists from the warmer and drier region of the PNM, while valuing livestock products more crucial for increasing pastoralism resilience among pastoralists from the colder region. The fact that most shepherding territory is located within a protected area that is under national administration could explain why in both consultations, priority was also given to large scale adaptations such as building water reservoirs, planting trees or implementing early weather warning systems. However, this result could also be due to individual strategies already being addressed and becoming less significant when compared to other major adaptations.

The stakeholders workshop confirmed some of the pastoralists perceptions on bureaucratic and legislative challenges to improve animal housing conditions or implementing water recovery systems. Though technology may benefit pastoral adaptations to climate change (Arjjumend 2018), in the PNM context, local protected area laws are somehow prohibitive. Moreover, other difficulties pointed out by stakeholders address the fact that many national strategies and policies are developed for pastoralism at a different scale than that of the PNM.

This investigation shows that pastoralists in PNM continue to adapt as they have done for decades, though we are unsure if these responses are enough to maintain the activity in times of accelerated and larger magnitude changes (Galvin, 2009). Indeed, worries emerged regarding the future of this traditional activity facing the impacts of a warmer and drier landscape, and political and social challenges (ex. unsuitable common agricultural policy, rural abandonment). Nevertheless, we hope that our research strategy of bringing together knowledge from pastoralists, stakeholders and scientists - "hybrid knowledge" (Dean et al. 2024) - will contribute to policy discussions at the regional and national levels on the complex Mediterranean pastoral systems and the need for climate change mitigation and coping strategies.

Aboriginal and white pastoralist history — the positive stories

Kelly, DM

University of Southern Queensland

Key words: Aboriginal people; Pastoralist; Race; Positive relationships; Nuanced history

Abstract
This paper examines the complex and often overlooked positive relationships between Aboriginal communities and white pastoralists in Australia. Narratives surrounding colonialism tend to focus on dispossession and conflict, yet there is a body of evidence that indicates some relationships were characterised by mutual respect, cooperation, and friendship. Using historical accounts, oral histories, and firsthand testimonies, this paper explores the diverse experiences of Aboriginal and white settler interactions, revealing a more nuanced history than is often presented.

The research highlights that while the overarching history of colonisation led to massive suffering for Aboriginal communities, the early pastoral era was marked by a variety of experiences, from oppression to collaboration. Through an examination of primary sources, this study contributes to a broader understanding of Aboriginal-settler relations, moving beyond simple binaries of conflict or harmony.

The importance of not simply accepting polarised positions about Australia's history is highlighted, as the reality of the situation was usually more complex. A deeper understanding comes from listening to alternative viewpoints about our shared history and discussing how we move forward together.

Introduction
The dominant narratives about Australian Aboriginal history since 1788 tend to emphasise dispossession, violence, and ongoing struggles for rights and recognition. While these stories are true and ubiquitous they can overshadow accounts of cooperation, friendships and nuanced relationships between Aboriginal people and white pastoralists. This paper seeks to highlight these positive perspectives, demonstrating that historical interactions were not uniformly antagonistic or destructive.

Historically, Aboriginal people's own oral histories reveal this dichotomy. Not all Aboriginal people working in the pastoral industry viewed white pastoralists as the enemy. Certain station managers and landowners are remembered with respect for their fairness, predictable treatment, or willingness to intervene on behalf of Aboriginal workers (Ross 1990; Ross and Bray 1989). Even today, many Aboriginal people want to talk about and acknowledge the pain of the past, and they also want to find a way forward.

This paper argues that Aboriginal-settler interactions in Australia cannot be reduced to a single narrative; relationships were not only shaped by the frontier wars, the disposition of land and discrimination. Dreadful events did happen, and the detrimental legacy lingers. Nonetheless, race relations need to be understood through a spectrum of experiences that reflect the diversity of individual relationships, shaped by time, geography, and personal attitudes. In the early days of settlement, and on stations today, enduring friendships and mutual respect does occur with some Aboriginal people and white pastoralists.

Methods

This study draws from four primary sources to examine historical relationships between Aboriginal people and white settlers. First, it draws on the writings of Alice Duncan-Kemp, whose detailed recollections, papers and books provide insight into her experiences growing up in the Channel Country alongside Aboriginal people and continuing to live most of her life in south-west Queensland rangelands (e.g. Duncan-Kemp 1961). The second data source is oral histories recorded by social scientist Helen Ross and a Warmun community member, Gija woman and language teacher Eileen Bray. These document Aboriginal perspectives on their interactions with white settlers in Kija country in the East Kimberley (Ross 1990; Ross and Bray 1989). Thirdly, this paper includes information from two interviews done by the author: Interview 1 with an Aboriginal woman and Interview 2 with a white descendant of a pastoralist. These offer personal accounts and reflections of family experiences in the rangelands and rural regions of eastern Australia. All these accounts support the premise that Aboriginal people and white pastoralists have had positive relationships with each other.

The qualitative data from these sources allows for an exploration of relationships across different regions and time periods. This paper does not claim to present a comprehensive review, but it highlights key themes that emerge from firsthand testimonies and recorded histories, which indicate that race relations are complex and nuanced.

Quotations used in this paper reflect the attitudes and language of settlers from the late 1800s and early 1900s, a period of pastoral expansion in Australia. This language, while confronting by today's standards, is retained here to provide an authentic representation of historical contexts.

Results

Despite the dominant narrative about dispossession of land and the enduring legacy of colonialism, positive relations did occur between Aboriginal people and early white settlers and pastoralists. These are largely unrecognised, especially in common parlance where the dialogue is often divisive.

Respect for Aboriginal culture

Some settlers respected Aboriginal people and their customs, even integrating these into their lives at times. In her book, *Our Channel Country*, Alice Duncan-Kemp explains that her parents taught her and her sisters to "*respect the Aborigines and insisted that we observe their laws and their rights to the vast area – their hunting-grounds and their only home – on which our stock depastured*" (Duncan-Kemp 1961 p232). She went on to describe that as children they '*were severely punished*' if they transgressed cultural boundaries (Duncan-Kemp 1961 p232). She had a deep understanding of Aboriginal people and their culture, as she spent considerable time wandering the country with Aboriginal people as a child, as she explains:

"We were placed under the care of Mary Ann, and Mother made her personally responsible for our welfare and safety. Mary Ann appreciated and vindicated the trust and confidence placed in her" (Duncan-Kemp 1961 p209).

George Debney of neighbouring Monkira Station was another settler who "treated and recognised the aboriginals as human, every black near and far loved Debney … 'Muluh-bu' they called him, 'the Very Wise One'" (Duncan-Kemp 1961 p137). Alice Duncan-Kemp recalled that he spoke 30 Aboriginal dialects, and "he could tell from a broken spearhead or the print of a bare foot what man has passed that way and to what tribe he belonged" (Duncan-Kemp 1961 p136).

Similarly, the Tamblyn family in central-west Queensland respected Aboriginal traditions by allowing corroborees to occur undisturbed. Elizabeth Tamblyn, William Lake Tamblyn's mother, ensured that white settlers stayed indoors during these ceremonies, recognising their cultural significance (Interview 2 2024).

Close friendships were not always desired, as explained by an Aboriginal woman (Interview 1 2024) about her father and grandfather who were Gunditjmara (south-western Victoria), living on their country:

“(The settlers) didn't talk to them much. But they were left alone … they had a good business in the timber industry; they made ends meet” (Interview 1 2024).

This aligns with what Duncan-Kemp said: “The aborigines did not intrude upon the European—the blacks never intrude. They only asked to be left alone (Duncan-Kemp 1961 p232).

Some Aboriginal knowledge and Law are considered private, sometimes it is ‘women’s business’ or ‘men’s business’; sometimes it is only for those who had reached a certain level of knowledge, of lore (Hicks 2020). As such, white people are not privy to many customs and knowledge.

Respect for Aboriginal customs, however, was not uniform. In the early days of establishing pastoral stations, many settlers disregarded traditional laws, often leading to conflict. “*Clashes with the blacks were a very real feature in the early pioneer days, but I have not mentioned anything of them because in my day such a thing was only a very remote possibility”* (Duncan-Kemp 1961 p232). However, those who respected Aboriginal culture and practices found ways to coexist more peacefully. Alice Duncan-Kemp's writings provide valuable insights into the cooperative relationships between settlers and Aboriginal people in early 20th-century Australia. She explains that keeping harmony meant adhering to customs, and that she:

> “owed so much to our parents training and the [Aboriginal women’s] finesse, and that to sit (at night by a fire) with the blacks a friendly distance away squatting over theirs, work being over, while the exchange of small talk, taking in the daily doings black and white, is the only sure way of keeping harmony and friendship” (Duncan-Kemp 1961 p116).

Such an understanding of Aboriginal culture and Debney’s ability to read country would have enhanced local Aboriginal people’s respect for him (Duncan-Kemp 1961). These accounts suggest that settlers and pastoralists who respected Aboriginal practices were able to coexist and foster cross-cultural exchanges, at least to some degree, but the depth of friendship is unknown.

Aboriginal Knowledge

Duncan-Kemp reflects on her appreciation for Aboriginal knowledge, noting that “I am grateful to the aborigines for what I learned from them of the good earth and its harvest, of human values and of dignity and decency —and reality” (Duncan-Kemp 1961 p236). She goes on to say explain that:

> “a very important side to Mary Ann’s activities … was the office of gdanaja or herbalist … Mary Ann possessed a great knowledge of the many divisions of the flower calendar and its intricate workings … some of this knowledge she passed on to her beloved ‘mississees’” (Duncan-Kemp 1961 p210-211).

Early settlers in Australia’s rangelands probably relied on Aboriginal knowledge to navigate and survive the harsh landscape more than is reported. Alice Duncan-Kemp acknowledged this in her writings, stating, “*The natives have been a wonderful asset to the settlers, without them, progress would have been impossible*” (Duncan-Kemp 1961 p233).

This perspective is reinforced by the descendant of Walter Lake Tamblyn, who was known to go walk-about with the Aboriginal people; sharing of food and reciprocity between ‘black’ and ‘white’ were a way of surviving in harsh environments and conditions, according to this interviewee. Such accounts challenge the simplistic notion that Aboriginal people were merely passive victims of colonial expansion. Instead, they actively shaped settler experiences and, in some cases, ensured their survival.

Aboriginal people's understanding of their land made them experts at navigation, finding food and water, forecasting seasonal conditions compared to white settlers who have arrived in Australia much more recently. While settlers often imposed their own European livestock practices, some came to appreciate the traditional knowledge of Aboriginal communities, particularly in relation to land use and resource management.

'Good Kartiya'

Oral histories collected by Ross and Bray reveal that Aboriginal people remembered certain white pastoralists as 'good kartiya' (good white people), individuals known for treating Aboriginal workers fairly and predictably, and in some cases, intervening on their behalf. Ross notes that "*the non-Aborigines who treated Aboriginal people well, and especially those who were willing to intervene on their behalf, are remembered with special affection*" (Ross and Bray 1989 p63). Among the earliest remembered were Sam and Arthur Muggleton, whom Aboriginal people recalled as encouraging settlement at Frog Hollow in north-western Australia as a refuge and providing meat, after 1905 (Jack Britten, 'Frog Hollow' in Ross and Bray 1989 p28-29).

Over time, the standards for what constituted 'good kartiya' and 'bad kartiya' evolved. As more pastoralists took active steps to intervene on behalf of Aboriginal workers, positive relationships like those at Frog Hollow became more common. Meanwhile, 'bad kartiya' remained, but their level of harshness gradually declined as expectations shifted (Ross and Bray 1989 p37). These comments indicate that perceptions change over time, adding to the complexity of race relations.

Nuanced Government Relations

The relationships between Aboriginal people and Government officials in the rangelands, had similarities to those between white settlers and Aboriginal people – they were far from uniform. Police behaviour varied more than is often acknowledged. The role of outback 'Native Police' force is documented in a harrowing account by David Marr (2023), who acknowledged the violent history of some of his forebears, with names, dates and crimes committed documented in early newspapers. Other accounts discuss the role of the Native Police in Queensland (e.g. Richards 2008; Roberts 2005; Walker *et al.* 2023), and elsewhere in Australia (e.g. Foster & Nettelbeck 2012; National Museum of Australia 2025). While many officers were complicit in violence, there were instances where police intervened to protect Aboriginal people. Ross and Bray (1989) outline several examples of positive relationships from the oral histories they collected, for example: Constable Flinders, who worked at Turkey Creek from 1914 to 1918 and intervened to prevent violence (Ross 1989 p37). Likewise, in the 1930s and 1940s, some pastoralists took active steps to defend Aboriginal employees. Jimmy Klein, manager of Texas Downs, stood up for Aboriginal workers and, in one account, saved a man from being shot by a white man after a fight (Bob Nyalcas, "Jimmy Klein" and "Violet Valley walkout" in Ross and Bray 1989 p63-64).

These examples illustrate that, while the broader colonial system was built on dispossession and control, and many massacres are documented, there were individual settlers and authorities who treated Aboriginal people humanely and even with kindness. The shifting expectations of fairness and respect over time also reflect the changing dynamics of Aboriginal-settler relations, as Aboriginal people increasingly asserted their rights and demanded better treatment.

Conclusions

Historical relationships between Aboriginal people and white pastoralists were complex and diverse. While the broader colonial project involved dispossession and violence, some individual relationships – especially after the initial dispossession phase - were marked by cooperation, mutual respect, and cultural exchange. Both parties appear to have been active in building the relationships, and the Aboriginal people had some agency in creating these relationships.

Recognising these nuanced histories does not negate the injustices faced by Aboriginal communities, but it does add depth to our understanding of Australia's colonial past. Having the difficult conversations about race relations, and about our history, helps us all understand the world from someone's perspective. Respecting our cultural differences is critical for society to move forward, and to bring harmony and build resilience in communities in the rangelands and beyond.

The challenge today is to integrate these perspectives into contemporary discussions on land rights and reconciliation, moving beyond simplistic narratives to acknowledge the full spectrum of historical experiences. Further research into personal diaries, oral histories, and archival materials will be essential in painting a more complete picture of Aboriginal-settler interactions.

Acknowledgements
Thank you to interviewees, Judith Standen and Kari Anderson, who provided me with stories about their parents, grandparents and earlier forebears, during our interviews. Thank you to Helen Ross for sharing her work and oral histories from the East Kimberley and reviewing my summary. Thank you also to Lorraine McKellar (Gorringe), a Mithaka lady whose forebears knew Alica Duncan-Kemp, for checking my interpretation of the relationships between Aboriginal and white settlers in far south-west Queensland. All of your insights and understanding of history provided the evidence for this paper.

Key lessons learned when supporting Indigenous scholars and communities during co-creation of knowledge

Reid, RS

Colorado State University, Fort Collins, Colorado, 80523, USA; robin.reid@colostate.edu

Key words: Co-production; co-generation; participatory; ethics

Abstract

This paper addresses the call, made by Indigenous scientists and knowledge keepers, for transformative change in western science by creating a new model of science based on relationships and reciprocity (Hird et al. 2023, David-Chavez et al. 2024). This transformation focuses on the rights of Indigenous communities and Nations when they co-create/co-generate/co-produce knowledge with non-Indigenous partners. Indigenous governance of research and practice includes development of relation-based scientific models, clear data sovereignty and governance, full inclusion of communities in all aspects of the research, cross-cultural learning, and development of safe spaces on science-community teams (Hird et al 2023, David-Chavez et al 2024). Here, I describe key lessons of doing this work, reflecting on western science and Indigenous approaches, using examples from pastoral lands in Africa and Asia and non-pastoral lands in the United States.

Introduction

Western scientists encounter many challenges when 'co-producing' knowledge with communities and other societal partners, attempting to blend western scientific knowledge with the broader knowledge of traditional knowledge keepers, Indigenous scientists, policy makers, practitioners and others in society (Chambers et al. 2021, Wyborn et al. 2019, Reid et al. 2016). Many co-production (often called co-generation or co-creation) initiatives face imbalances in power concerning whose knowledge or worldview counts, who generates knowledge and how, and who has access to that knowledge. In lands where colonial powers stole Indigenous land and forcibly assimilated Indigenous cultures (as in North America, Australia, New Zealand), these power imbalances are particularly acute when Indigenous and non-Indigenous participants attempt to blend their knowledge systems today. These power imbalances also appear in western scientific institutions and academia, where 'the colonial science paradigm' often devalues Indigenous knowledge, science and practice (David-Chavez et al. 2024). The objective of this paper is to describe lessons learned when blending Indigenous and non-Indigenous participants on teams who co-create knowledge about pastoral and non-pastoral peoples and their lands in Africa, Asia and North America.

Approach: Positionality and reflection on current practice

In this paper, my positionality matters. I am a female Caucasian, non-Indigenous social-ecological scientist from the land currently called the United States. This paper is based on my experience working for 25 years with Indigenous pastoral people in Kenya, Tanzania, and Mongolia. More recently, it is based on a decade working on mixed Indigenous and non-Indigenous teams of scholars and practitioners on coproduction/cogeneration in North America. Here, I summarize lessons learned from these experiences and refer to selected published works by Indigenous scholars and practitioners, codes of ethics, and international agreements. I organize the next section according to key core values and actionable methods described in Dominique David-Chavez and colleague's *relational science model for Indigenous research* (David-Chavez et al. 2024) and Coen Hird and colleague's 'recovery guide for settler-colonial scientists' (Hird et al. 2023). I then reflect on the practice of my research teams in relation to these Indigenous models, drawing out key lessons that would deepen our current practice. Due to text limitations here, I include some additional important quotes from Indigenous and non-Indigenous scholars and a few additional selected references in Table 1. See key papers cited here as a taste of the breadth and richness of current Indigenous scholarship.

Table 1. Key quotes from Indigenous scholars and Elders and selected additional references.

Key quotes from Indigenous scholars and Elders	
Hikuroa et al. 2011 (comparing Maori traditional knowledge and western science)	'Both mātauranga Māori and science are bodies of knowledge methodically created, contextualised within a world view…. While there are many similarities between mātauranga Māori and science, it is important that the tools of one are not used to analyse and understand the foundations of another (Hikuroa et al. 2011).'
Liboiron. 2021	'Every morning when I put on my lab coat, I have decisions to make. How will we do science today? How will we work against scientific premises that separate humans from Nature, that envision natural relations as universal, and that assume access to Indigenous Land, especially when so much of our scientific training has primed us to reproduce these things?'
Watego. 2021 in Hird et al (2024)	Watego (Mununjali, South Sea Islander) writes: 'We simply don't need more texts that teach whitefullas about us on their terms'.
Hird et al. 2023	• 'Academic knowledge systems….preserve a power imbalance with Indigenous ways of knowing and being, often by omitting, misinterpreting, extracting from and devaluing Indigenous knowledges' • 'Prioritising community collaborations, relationships and trust as indicators of researcher success, as well as working with and empowering Indigenous communities to make sure they are upholding community expectations, can increase ethical science among scholars (AIATSIS 2020)'. • '….when Indigenous scholars are 'forced into roles as 'harmonisers', 'facilitators' and 'translators' to accommodate the need to bring people with us to effectively disrupt colonial norms, Indigenous scholars can experience 'translation exhaustion.' • 'Settler-scholars should realise they work on occupied lands and move past land acknowledgements, instead asking what is required of them should they want to become 'proper guests' (Stewart-Ambo and Yang, 2021).' • **'Derridean flip…:** Did that recent 'scientific' finding really prove ancient knowledge was right?' • **'Columbusing knowledges :** Claiming scientific 'discovery' of concepts, practices, species, etc., while failing to credit or acknowledge long-standing Indigenous knowledge and understandings thereof.' • 'Interrogate how your work upholds settler-colonial capitalist institutions which exist and benefit off the continued oppression of Indigenous peoples and their lands.'

A Call for Change and the Relational Science Model for Indigenous Research

The need for transformative and profound change in western science

While there are many calls to broaden science to include interdisciplinary and transdisciplinary approaches, calls from Indigenous scholars ask non-Indigenous scientists to dig much deeper (Hird et al. 2023). They ask that western scientists recognize that their science is a construct of Western European culture and thus is only one way to create knowledge. They ask us to challenge our assumptions about the superiority of western science by recognizing that Indigenous knowledge is often the basis of western science. More specifically, they ask that western scientists ask permission whenever we work on (often stolen) Indigenous lands, treat their more-than-human research subjects as relations not objects, stop attempting to extract or assimilate Indigenous knowledges, and give full credit to longstanding Indigenous understandings. They ask us to resolve power imbalances between our knowledge systems by building equitable partnerships and uncovering how our 'work upholds settler-colonial capitalist institutions which exist and benefit off the continued oppression of Indigenous peoples and their lands' (Hird et al. 2023, p. 3). Answering this call can unleash innovation and problem solving potential (David-Chavez et al. 2024).

Commit to change: Deep listening, study, and learning

Here, Hird and colleagues (2023, p. 3) say, 'Continue to educate yourself and others, participate, and commit to working with Indigenous peoples towards an anti-colonial and inclusive science paradigm. Centre Indigenous rights as a responsibility.' In our work in Africa and Mongolia (where colonial history is different than in North America), this meant constructing, learning and working on teams with equitable participation of local/Indigenous scientists and community members. These teams were led by foreign researchers with decades of experience working with local communities as individual scientists and then on large, interdisciplinary/transdisciplinary teams (Fernández-Giménez et al. 2019, Reid et al. 2021). In North America, the non-Indigenous scientists on our teams embarked on a continual practice of deepening our understanding of settler colonialism, Indigenous knowledge/philosophy, intergenerational trauma, and extractive relationships scientists still have with Indigenous peoples. Despite these efforts, we found that we will never 'know' or fully understand, but we are clear that it is our job to educate ourselves as deeply as possible.

Integrity: 'Honor ethical responsibilities to communities impacted by research'

The first core relational value of the relational science model of Indigenous research is *integrity*. Here, David-Chavez explains: 'By explicitly centering relational values, we are emphasizing the fundamental importance of building, nurturing, and sustaining relationships between researchers and community to enable more ethical and effective science research practice…'. This value asks all researchers to 'cause no harm' and follow more formal ethical protocols (David-Chavez et al. 2024). Ethical protocols are based on the UN Declaration of the

Rights of Indigenous Peoples which include rights to equality, self-determination, self-government, liberty, security of person, secure access to traditional lands and waters, and restitution for stolen lands (UNDRIP 2007). These protocols expand on the Belmont ethical principles for transdisciplinary research (justice, beneficence, respect for persons) to include appropriate representation, self-determination, reciprocity and deference, as well as beyond-human ethics (Wilmer et al. 2021). Actionable methods include understanding and abiding by the Indigenous rights, obtaining 'free, prior and informed consent' before embarking on research, following the CARE principles (Carroll et al. 2020) and Indigenous/customary data protocols, and working with tribal advisory councils. One formal ethics code is the Australian AIATSIS Code (AIATSIS 2020); see others in (David-Chavez et al. 2024).

When working in Africa and Asia, our teams did not encounter Indigenous communities with formalized ethical protocols, and thus followed Western European-dominated ethics in these cases. I wish we had known about much of the work described here, like the engagement in ethical spaces (Ermine 2007) and the expansion of the Belmont principles (Wilmer et al. 2021). More recently, working with Alaska Native communities, we adopted the Circumpolar Inuit Protocols for Equitable and Ethical Engagement (ICC 2022) in our sustainable harvest research (Heeringa et al. 2019). In our current work with global Indigenous mountain communities, we are following the guidelines laid out in David-Chavez et al. (2024).

Respect: 'Sustain or restore Indigenous governance of Indigenous research and data'

Next, David-Chavez and team (2024) lay the foundation for fundamental change in western science by emphasizing the value of *respect.* They suggest western scientists stop extracting and assimilating Indigenous knowledges, instead deferring to Indigenous knowledges and knowledge keepers. Western scientists need to ensure Indigenous Peoples control the research process and its outputs and benefit from its outcomes. Actionable methods include listening deeply to community needs, using classic participatory action methods, uncovering barriers to community leadership, and establishing formal research agreements. Our western science approaches to co-production were deeply built on this core value. However, we did not always establish community advisory bodies. We also found 'outcome mapping' to be particularly useful where outcomes desired by community members drive the research goals (Reid et al. 2016).

Humility: 'Support opportunities for shared learning'

Humility is a third core relational value that helps 'us to observe…and support dialogue between worlds, rather than holding one above the other' (Ermine 2007, David-Chavez et al. 2024). It allows deep social learning and capacity building among researchers and communities alike. Examples of actionable methods include adaptive experiential learning through discussions during field hikes, storywork through focus groups, critical reflexivity practice, and participatory mapping.

In our work, we encouraged our graduate students to use classic ethnographic techniques to learn how to adapt their research to community needs (see Pickering in (Reid et al. 2021)). Some students arrived in an Indigenous community with a research topic based on deep reading, but then recreated their research topic and methods after months of consultation and multiple seasons working with community members. Also, in my experience, this is the most exciting and rewarding part of flipping the classic western science model, where I have found the deepest learning and most profound innovation.

Reciprocity: 'Ensure research process, outputs and outcomes benefit community'

A fourth core relational value is *reciprocity*. David-Chavez and team (2024) describe how research can ensure Indigenous communities are primary beneficiaries of research process, outputs and outcomes. Key actionable methods here include developing formal community research governance roles (e.g., community advisory groups); sharing funding equitably; and adopting Indigenous methodologies including data governance protocols (which control the collection and application of data about Indigenous lands and peoples). They also involve engaging Indigenous youth who will be future stewards of the land (see (Pickering Sherman and Sherman 2010)); community review of raw data and discussions of interpretation; Indigenous authorship of outputs; providing accessible data and outputs that are desired by Indigenous communities; and partnership benefits like workshops with story sharing/focus group discussions and local presentations.

These approaches are where the western science model of co-production, when implemented fully, most resembles David-Chavez and team's model. In our work in Africa, we flipped the usual approach to western science so that it was not driven from the needs of the researcher's intellectual development or an outside institution, rather it was driven by the needs of the community our research sought to serve (Reid et al. 2016, Reid et al. 2021). Of course, this approach applies more broadly than work with Indigenous Peoples alone, and includes our approach with communities of fish or trees, policy makers or farmers, and others. From a western science perspective, this means developing the focus, questions, methods, protocols of the research, data visualization, interpretation and products with Indigenous communities. It means spending significant time in community before finalizing the research topic to have many community consultations to ensure that research outputs and outcomes benefit the community. It can also mean aiding Indigenous Peoples as they serve as guardians for our more-than-human relatives. We also collected information together with and under the advice of community members. We interpreted what we found and designed and co-authored outputs together (journal articles, films, policy briefs, stories, etc.). We also discussed and anticipated possible short- and long-term outcomes and impacts and planned for them. Our graduate students often focused their efforts on initial community consultations and then returning results in feedback workshops (Reid et al. 2021).

A last key lesson: Do the hard work of providing safety for all involved

Finally, one the of the most important actions for western scientists to take is to stand up when non-Indigenous scholars are offensive to Indigenous scholars. This is particularly important when speaking up is hard to do. In our work, we faced this need when a western scientist colleague lashed out when they were asked to listen and no longer dominate. It also occurred when a powerful scientific institution removed an Indigenous colleague from a national committee when they spoke out about inappropriate consultation with Native American tribes (Mervis and Ortega 2024). Doing so not only provides support to Indigenous colleagues and community members, but also relieves them of the burden of speaking out themselves. Our current team practice is to work with indigenous facilitators to ensure safe cross-cultural interactions among our scientific team and agree on and adhere to joint community values for all our work.

Conclusions/Implications

In my view, co-production/braiding of knowledge among different knowledge systems is a pathway to begin to repair past and current harms caused by our approach to western science. It also unlocks great problem solving potential. The deep trauma caused by colonization (and western science approaches) created the dire need to establish ethical standards for all interactions of non-Indigenous scholars with Indigenous scholars. These wise values and methods could be applied, in principle, to interactions with all Indigenous and local peoples, including pastoral peoples. As such, 'business-as-usual' in western science is now old thinking, thanks to the leadership of a new generation of Indigenous scholars and their supporting communities.

Acknowledgements

I am deeply honored to work with and learn from many Indigenous scholars and Elders, including Ed Iron Cloud, Marie Gladue, Dominique David-Chavez, Timberley Roane, Kyle Whyte, Heather Sauyaq Gordon, Ron Trosper, Roe Bubar, Shatta Mejia, Jennifer Wolf, Sam Barr, Rosie Cayou James, Freddie Lane, Jay Julius, Robin Wall Kimmerer, Linda Tuhiwai Smith, David Nkedianye, Dickson Kaelo and Nickson Parmisa.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

International cooperation to improve forage supply in grasslands in Kenya and Tanzania

Guzmán, FD[1]; Ledesma, RR[1]; Alberghini, JP[1]; Nenkari, H[2]; Sangula, A[3]; Okore, C[4]; Kidake, B[5]

[1] National Institute of Agricultural Technology, Argentina; [2] Ministry of Agriculture and Livestock development, Kenya; [3] Veterinary Services Foot-and-Mouth Disease National Reference Laboratory, Embakasi; [4] Ministry of Agriculture and Livestock development, Kenya; [5] Kenia Agriculture and Livestock Research Organisation.

Key words: international project; participatory strategies; livestock production; pasture management; Arid and Semiarid Lands.

Abstract:
Grasslands and savannas cover a significant area of the earth and are home to much biodiversity and livestock, including cows, goats, sheep, and other animals. Livestock production in these ecosystems is characterized by a low supply of forage mainly due to advanced erosion processes, overgrazing, shrub invasion, lack of availability of quality grass seeds and the concomitant decline of palatable species. The purpose of this paper is to describe the exchanges and highlight the potential for collaboration for the construction of knowledge, in science and technology, focused on livestock production in the arid and semi-arid zones (ASALs) of Kenya and Tanzania. Between 2017 and 2022, a bilateral technical cooperation project promoted by the Argentine Fund for International Cooperation (FO.AR) was carried out called: "Improvement of livestock production in arid and semi-arid areas of Kenya". The activities of this project focused on the participatory identification of the main constraints affecting smallholder livestock production. The project involved Kenyan researchers, extension workers, national and county government livestock officials, and livestock producers. Since 2020, different Tanzanian institutions (Ministries) have resumed their relationships with Argentine cooperation agencies to participate in several training proposals to improve the supply of forage for livestock systems in Kenya and Tanzania. During the project, six missions were carried out, four from Argentina to Kenya and two from Kenya to Argentina, in addition to participatory workshops for the identification of constraints and proposals for strategies to address these constraints. The German government, which has a presence in the two African countries, had shown interest in these activities and in 2022 a new project was approved: "Strengthening capacity building to improve smallholder farming livestock systems and contribute to agri-food sustainability in Kenya and Tanzania". This project is financed by Germany and is executed by the following institutions: Kenyan Ministry of Agriculture, Livestock, Fisheries and Cooperatives, Tanzania Ministry of Livestock and Fisheries, Argentine Agency for International Cooperation and White Helmets Humanitarian Assistance (National Directorate of International Cooperation), Ministry of Foreign Affairs, International Trade and Worship; Ministry of Agriculture, Livestock and Fisheries; the National Institute of Agricultural Technology (INTA), the Tanzania Livestock Research Institute (TALIRI) and the Kenya Agriculture and Livestock Research Organization (KALRO) and livestock producer organizations at provincial and/or municipal (county) levels.

Introduction
Savannas and grasslands occupy a fifth of the earth's land surface witha large human population, and livestock and wild herbivores inhabit these biomes. Grasslands are known as seedbeds for the ancestors of cereal crops and the domestication of cattle, donkeys, goats, and sheep. Grasslands have been largely considered as a carbon reserve (Curtin and Western, 2005) and are highly dynamic ecosystems because of variable rainfall, soil nutrient levels, fire and herbivory (Rutherford et al., 2012). Grassland states vary from sites with a range condition with ample herbaceous cover, perennial grasses and scattered trees to states with a poor cover of annual grasses, absence of perennial and palatable grasses, a high proportion of bare soil and/or often bush encroached (Rutherford et al., 2012).

In arid and semi-arid lands (ASALs), where the climate is less suitable for crops, pastoralism is the main livestock system and occurs in 40% of Africa's terrestrial area (ILRI, 2021). Pastoralism contributes between 10 and 44% of the gross domestic product (GDP) of African countries with approximately 1.3 billion people benefiting from the livestock value chain. Also, over 75% of cattle herds in Kenya and 90% in Tanzania are kept by pastoralists who supply the bulk of meat consumed in those countries (Nyariki and Amwata 2019). Cattle production of small farmers in ASALs in Kenya and Tanzania and Arid and Semiarid Chaco regions in Argentina present common production and social features, for example, the lack of forage, the loss of native palatable grasses and forbs, the increasing area of bare ground, and bush encroachment caused mainly by overgrazing, deforestation and rainfall variability (Mureithi et al.2015).

The trajectories of knowledge development, including tacit and scientific knowledge, when shared, allows an accelerated knowledge growth amongst all the actors involved, facilitating learning about strategies to overcome common constraints. The approach focuses on the "win-win" strategy, where everyone learns from each other's experience.

In 2017, an international cooperation strategy began with the aim of improving livestock production which includes two stages, a first that reached until 2023, linking Argentina and Kenya, in a project founded by the Argentinian Fund for International Cooperation, with the main objective of exchanging experiences in research and extension, technology transfer and training in grazing management and animal nutrition contributing to security and food sovereignty, while taking care of the available natural resources.

At the end of 2023, a second stage in cooperation began with the start of a second project, founded by the German International Cooperation Agency (GiZ), linking Argentina, Kenya and Tanzania, with the main objective of strengthening the technical capacity necessary to increase meat and milk production in livestock systems of smallholder farming.

Methods
The methodology consists of:

1) International missions where key people visited INTA Agricultural Experimental Stations (EEAs), research centrs of the Kenyan Agriculture and Livestock Research Organization (KALRO), research centres of the Tanzanian Livestock Research Organization (TALIRI), farms, companies producing fodder, pasture seeds, balanced feed and companies for the manufacture and maintenance of agricultural machinery and tools..

2) Face-to-face workshops with farmers, researchers, extensionists and public policy decision-makers, to identify constraints and challenges of livestock production systems and identify strategies to overcome them.

3) Virtual workshops with researchers and extension workers from the countries involved working cooperatively dealing with specific topics of livestock production of ASALs aimed at sharing technological proposals.

4) Meetings with public policy decision-makers in the field of livestock production of ASALs.

5) Implementation of demonstration plots with appropriate technologies for forage management.

Results

From 2017 to 2023, a first cooperative project was carried out between Argentina and Kenya, seven missions were carried out, four from Argentina to Kenya and three from Kenya to Argentina. Visits to KALRO, farms, machinery workshops and enterprises dedicated to produce balanced foods were made in Kenya. During the visits to Argentina, EEAs (spell out) and Research Institutes of INTA and private farms were visited. In addition, both during the visits to Kenya and Argentina, meetings were held with public officials from the livestock areas of the provinces and counties visited. These exchanges aimed to know and understand the challenges of the livestock producers of the ASALs, the technological developments of the science and technology institutions aimed at overcoming these challenges and the strategies developed by the private sector.

Two participatory workshops were held, the first in 2019 in Isiolo city in Kenya, to identify the main restrictions, opportunities and solutions that arise in livestock production in the ASALs of Kenya. Thirty-seven people participated and they identified the following restrictions: overgrazing, high stocking rate, bush encroachment, land degradation and land use change, non-implementation of grazing management plans, droughts and water scarcity, inadequate water harvesting structures, deforestation, weak connection between extension services and research activities, inadequate marketing information system, insecurity, competition for resources and poor intercounty linkages.

A second workshop was held in the frame of the GiZ founded project during November 2024 in Arusha city in Tanzania, to identify the main appropriate technologies to promote the improvement of the forage supply for pastoralists' and smallholders' livestock systems in the arid and semi-arid areas of Tanzania. Twenty-seven people participated. The methodology implemented was a foresight analysis and it was discussed that the main technologies should be oriented towards well defined land ownership by individuals, groups or company, developing of climate-smart approach technologies, effective invasive species strategy control, effective control of soil erosion, increased production of pasture seed and the development of water infrastructure for livestock.

Two virtual workshops were held with broad participation of researchers and extension workers discussing and analysing strategies to improve livestock systems in the ASALs of Kenya and in the Arid Chaco region of Argentina. Seven INTA research centres in Argentina in different provinces, three KALRO research centres in Kenya and the International Livestock Research Institute(ILRI) in Nairobi, and two Tanzanian Livestock Research Institutes in Tanzania were visited during the virtual workshops.

The design of two experimental-demonstration plots and its location were defined in the last mission made in November 2024 by the technical team of the three countries. The productivity (biomass) and seed production of 4 native species will be determined: Bush rye (*Enteropogon macrostachyus)*, Maasai love grass (*Eragrostis superba*), Horsetail grass (*Chloris roxburghiana*) and Foxtail grass (*Cenchrus ciliaris*). Also, an experiment to assess the effect of bush clearing by two methods was designed including 3 treatments: a) Control, without intervention: b) Manual bush removal and c) Mechanical treatment for shrubbing. The analysis of the investments, labour and administrative aspects were managed by the technicians with the support of personnel from GIZ. The plots were closedto domestic and wild animals, and have different areas.

Discussion

The characteristics of livestock farming in the ASALs of Kenya, Tanzania and the Arid Chaco of Argentina are similar, both from the natural conditions, the social actors involved, and the restrictions and challenges faced, although their historical trajectories are very different. Technological developments are similar, although with particularities in each country, which allow mutual learning by sharing experiences. While in the two African countries research and extension activities are separated between different institutions, in Argentina both are within the same institution, which favours dialogue and exchange. The exchange of experiences, discussion and analysis of strategies with practical learning in the visualization of the technological trajectories followed by each of the countries to achieve the resolution of common problems, is highly valued and tends to accelerate the process of development of technologies and its application in livestock systems.

Key words: community-based restoration; Indigenous peoples; ecological restoration; climate adaptation; seed-based restoration

Abstract
Seed-based restoration of degraded landscapes in dryland systems often fails to result in desired revegetation. Locally specific strategies are needed to overcome barriers to native plant establishment. To meet these challenges, we convened a collaborative team that emphasises relationship building, including scientists from the United States Geological Service (USGS), Colorado State University (CSU) and CSU Extension (CSUE) at the request of Ute Mountain Ute Chairman Heart to bring restoration research to Tribal lands in southwestern Colorado, USA. Our team has continued to focus on restoring ecosystem structure and function, improving productivity for grazing and ensuring access to cultural resources.

In 2020, collaboration with the Ute Mountain Ute Tribe (UMUT) began, and two experimental sites were established: a USGS RestoreNet (Field Trial Network for Dryland Restoration) plot and a culturally important location for hyperlocal seed-based restoration questions and treatments rooted in Indigenous knowledge systems. In the first phase, we explored local challenges and tested innovative approaches, informed by community input, Western scientific literature and traditional ecological knowledge. Using an intentionally scaled approach and rigorous scientific methods, the sites test climate-adaptive restoration treatments in 4-m^2 plots including ground modifications, seeding vs. outplanting seedlings, herbicide treatments to suppress invasive species, and others.

Preliminary results show effective restoration strategies include imprinting the landscape with pits, outplanted restoration islands and the importance of integrated invasive species management. Equally importantly, we have built relationships and met Tribal needs through education and outreach.

Since 2020, we have gained insight into the challenges and successes of working collaboratively across a land-grant university, tribal government, governmental institutions and other community groups. By honouring different perspectives and expertise, we are creating actionable science and building relationships essential to the restoration, future grazing and long-term health of arid systems on Tribal lands.

Introduction

Arid and semiarid (dryland) ecosystems cover roughly 40% of the earth's land surface, provide critical ecosystem services and are increasingly prone to degradation associated with climate change (Hoover et al. 2020). Following degradation, recruitment of native plants through natural recovery is often unsuccessful. Similarly, seed-based restoration in dryland systems often fails to result in desired revegetation (Shackelford et al. 2021). Barriers to native plant establishment from seed include water limitation, extreme temperatures, depleted soil and competition with invasive species (Shackelford et al. 2021). Acknowledging these challenges, we sought to explore reasonable treatments that could be applied at scale when attempting to restore lands in dryland ecosystems.

On Tribal lands, the challenges to restoration are exacerbated by the reduction of Indigenous peoples' sovereignty, land dispossession, ongoing displacement, oppression and heightened climate change vulnerabilities (Archuleta et al. 2015, Farrell et al. 2021). Recognising the multifaceted barriers to restoration, the team decided to investigate active restoration techniques on a small scale that could be practical and applied at the large scale needed for the region on rangelands. Locally specific, culturally informed and scientifically grounded strategies are needed to develop appropriate and effective restoration approaches (Wickham et al. 2022).

To meet these challenges, at the request of UMUT Chairman Heart to bring restoration research to Tribal lands in southwestern Colorado, we convened a collaborative team that emphasises relationship building, starting in 2021. This team includes staff from UMUT Environmental Programs, the Dryland Ecology and Management Lab at CSU, CSUE, and the United States Geological Survey (USGS) RestoreNet team. Building on the networked trials from the USGS RestoreNet team, we were able to install a RestoreNet research site incorporating treatments of interest to UMUT Environmental Programs staff to meet the needs of their restoration goals, that are appropriate for the environment and community cultural values (Laushman et al. 2022, Long et al. 2020). As we collaboratively developed potential treatments, we kept the goal of increasing forage for livestock grazing and the practical application of treatments in mind so successful treatments could be scaled in the future. Project collaborators were also able to openly communicate about the needs for staff funding and labour to make this project possible.

As the 10-year RestoreNet project continues, our team and projects have expanded beyond our initial rangeland restoration project. Building on RestoreNet, a second experiment site was established in 2022, at a culturally important location to test additional hyperlocal seed-based restoration questions and treatments rooted in Indigenous knowledge systems.

Methods

Frameworks and principles for collaborative restoration projects with Indigenous peoples

The collaborators in this project came with various levels of experience and expertise in working with traditional ecological knowledge, rangeland restoration, Land Grant Universities and/or Tribal Nations. We have looked to team members' experience as well as others who have demonstrated successful collaborations addressing ecological restoration and specifically collaborative projects with Tribal Nations (Wickham et al. 2022, Long et al. 2020). This project is one of many that are partnering U.S. academic institutions and government agencies, as well as their policies, protocols and scientific bodies of knowledge, to support the sovereignty and implementation of Indigenous knowledges. Throughout the project, the aim of researchers embedded in U.S. institutions is to provide resources and expertise while following the lead of the UMUT's community members and staff. By honouring and weaving these different ways of knowing, we work towards repairing relationships between human and ecological functions (Robinson et al. 2021).

Relationship building and goal setting

Building relationships and establishing new collaborative research projects has, in our experience, taken time and required consistency in the people and entities involved. CSU/CSUE staff's initial collaboration with the UMUT on rangeland restoration projects was due to chance meetings, planned organisational meetings, community listening sessions and persistence from both sides. These relationship-building efforts are what brought Chairman Heart to an online stakeholder meeting hosted by local, regional and on-campus CSU faculty introducing the idea and gauging community interest in a land restoration project. This meeting was followed by an in-person site tour and then a request to bring dryland restoration research to UMUT land (Laushman et al. 2022).

From ideas to implementation

Translating ideas to implementation would not have been possible without dedicated Tribal collaborators who continue to engage with this project and navigate Tribal approval processes. From the beginning, clear communication and expectations ensured we were able to meet each other's needs. Additionally, a data-sharing agreement to protect and describe when data could be shared or used between partners was a critical aspect of project development and ensuring findings from Tribal lands were shared in a manner that respects Tribal sovereignty.

Leveraging a regional restoration field trial network (RestoreNet) to meet local needs

First, in 2021, local, regional and on-campus faculty from CSU/CSUE and the Tribal staff collaborated with the USGS to establish a RestoreNet site (Havrilla et al. 2020, Laushman et al. 2022), a distributed dryland restoration field trial, on UMUT Tribal land to test restoration treatments of interest. Using an intentionally scaled approach and rigorous scientific methods, the sites test climate-adaptive restoration treatments in 4-m^2 plots including ground modifications, seeding vs. outplanting seedlings, and other locally identified treatments of interest including *Tamarisk sp.* (saltcedar, a common invasive tree in the area) mulch and polymer beads. As a large-scale networked restoration trial network RestoreNet, led by USGS in partnership with universities and a variety of research partners, tests consistent treatments across environmental gradients but also allows for additional local questions. A desire to ask additional hyperlocal questions outside the RestoreNet framework at a slightly more mesic site led to the establishment of a second experiment.

Place-based restoration trials at a culturally important site

Second, we established a separate field site for restoration research at a culturally important location to test additional hyperlocal seed-based restoration questions and treatments rooted in Indigenous knowledge systems. Treatments at this site included the use of locally available materials left over from cultural harvest practices, and low-tech rock structures rooted in Indigenous knowledge to slow and spread water (Martin et al. 2010). The strength of this project has been a focus on local placed-based treatments and culturally relevant practices valued by members of the team and the communities in which they live.

Results

RestoreNet

Preliminary results from the RestoreNet site demonstrate that imprinting pits (modelled after waffle gardens used by Indigenous peoples across the Southwest) and covering the soil with mulch have increased seed germination. These two techniques increase water retention and soil nutrient availability. Further, seedlings that were grown in a greenhouse, then outplanted to the site show promise, as a higher percentage of these seedlings have survived and flourished over the three years since the site was established than seeded species. This result indicates that restoration islands, a technique in which small groups of seedlings are planted, then self-seed to increase the native plant community, may be beneficial for restoration in the area (Davies et al. 2020).

Place-based restoration

While seeded species recruitment has been limited, this site has emphasised the need to consider integrated invasive species management as an essential aspect of restoration work at this location of cultural importance. Of the treatments tested, low-tech rock structures that slow and spread sheet water flows and coarse woody debris that creates favourable microclimates at the soil surface seem to be the most effective.

Meeting local needs

Through these projects, we have also gained insights on collaboration, building trust and respecting the many ways of knowing. We have learned that thoughtful consideration can make implementing new ideas more successful. Ensuring all partners are invited to participate throughout a process including in the planning process, implementation on site and to provide feedback as a plan is developed, ensures an investment and sense of ownership in the project's long-term success.

As a result of trust building, sharing and discussing results, we have also created interest in larger-scale studies and projects that can take what we have learnt and apply it at scale, leveraging what we have learnt about treatments and species success to be more successful with future restoration projects. Also, building relationships and discussing local needs led to the development of different types of collaboration to address further needs related to rangeland health and management. Through collaboratively organising educational workshops for ranchers or sourcing funding for rangeland monitoring, collaborations stemming from one rangeland research project have grown to include multiple projects to meet many different community-based goals.

Discussion

Since 2020, we have gained insight into the challenges and successes of working collaboratively across a land-grant university, Tribal government, governmental institutions and other community groups. By honouring different perspectives and expertise, we are creating actionable science and building relationships essential to the restoration, future grazing and long-term health of arid systems on tribal lands.

The continued efforts of many individuals led to effective working relationships. From this foundation, we can continue to further expand projects to meet the rangeland restoration needs of the Tribe. We can also reflect on our successes and struggles to continue to improve working relationships, community outreach and understanding the strengths that come from respecting many ways of knowing and the many ways we can understand, relate to and value rangelands.

Acknowledgements

We thank the UMUT, including Chairman Manuel Heart for leadership; Hannah Ertl for contributions to establish the research sites; and Farley Ketchum Sr., Ben Robinson and Scott Clow for continued collaboration and support. We thank the US Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) and USDA Northern Plains Climate Hub, Cooperative Ecosystem Studies Unit (CESU) (Award Number: NR223A750023C019) for providing the funds necessary to support research at the culturally important location.

Abstract
The substantial research gap between rangeland/livestock science and conservation biology/vegetation ecology has led to a shortage of evidence needed for grazing-related conservation management. Knowledge co-production and long-term knowledge partnerships between scientific and traditional knowledge could help fill this gap. We worked closely with traditional herders in Hungary (including co-design and co-publication) on understanding grazing behaviour of beef cattle on species-rich grasslands. We found that cattle grazing on species-rich pastures displayed at least 10 different behavioural elements as they encountered 117 forage species from highly desired (preferred) to rejected, with small discrimination error. Herders had broad knowledge of grazing desire and they consciously aimed to modify desire (modify selection behaviour, grazing preference) by slowing, stopping or redirecting the herd. Many of these have conservation benefits. We also prepared a global review on forage-related knowledge of herders based on scientific papers and video documentaries, and collaboratively discussed with traditional herders. We found 35 indicators used by herders to describe forage species. These indicators were used in context-specific management decisions, with a variety of objectives to optimize grazing.

Introduction
The substantial research gap between rangeland/livestock science and conservation biology/vegetation ecology has led to a shortage of evidence needed for grazing-related conservation management. Connecting scientific understanding with traditional ecological knowledge of local livestock keepers through knowledge co-production and knowledge partnership could help bridge research and knowledge gaps (see some example: Barani 2007, Biró et al. 2019, Reid et al. 2014, Schlecht et al. 2006).

An understanding of traditional ecological knowledge systems is increasingly acknowledged also as a means of helping to develop global, regional and national, but locally relevant policies (Sharifian et al. 2021, 2023). Pastoralists often use lands that are unsuitable for crops due to biophysical and climatic extremities and variabilities (Krätli and Schareika 2010, Manzano et al. 2021). Forage plants of pastures that are often unpredictable in availability (Molnár et al. 2020, Sharifian et al. 2023), are utilized by herding communities by applying locally relevant multigenerational knowledge. In this presentation we will show our study of the grazing behaviour (plant selection and avoidance) of beef cattle on species-rich lowland pastures in Central Europe (Molnár et al. 2020), and a global review of the forage-related knowledge of pastoralists and herders and how this knowledge is used in herd and pasture management (Sharifian et a. 2023).

Methods

We studied the grazing behaviour (plant selection and avoidance) of beef cattle (ca. 33 000 bites) on species-rich lowland pastures in Central Europe, as well as the related traditional herding practices. We also did >450 outdoor interviews with traditional herders about livestock behaviour, herders' decisions to modify grazing behaviour, and effects of modified grazing on pasture vegetation. The whole multi-year research was done in close collaboration with several key knowledgeable herders, starting with co-design of the research, doing data collection and data analysis and discussion together and finishing with co-publication (papers and conference presentations).

In the other study we analyzed the forage-related knowledge of pastoralists and herders by reviewing scientific papers (based on keyword search) and video documentaries (searching on the internet through keywords and directly contacting specialist researchers) with the original voices of herders on forage plants and indicators, their use in land management, and plant-livestock interactions. Semi-structured interviews were also conducted with key knowledge holders in Iran, Mongolia, Kenya, Poland and Hungary. The key results and conclusions were discussed again with two key knowledgeable herders before publication. We found 35 indicators used by herders to describe forage species and manage herds and pastures.

Results

We found that cattle grazing on species-rich pastures displayed at least 10 different behavioural elements as they encountered 117 forage species from highly desired (preferred) to rejected (Fig. 1., Molnár et al. 2020). The small discrimination error suggests that cattle recognize all listed plants 'by species'.

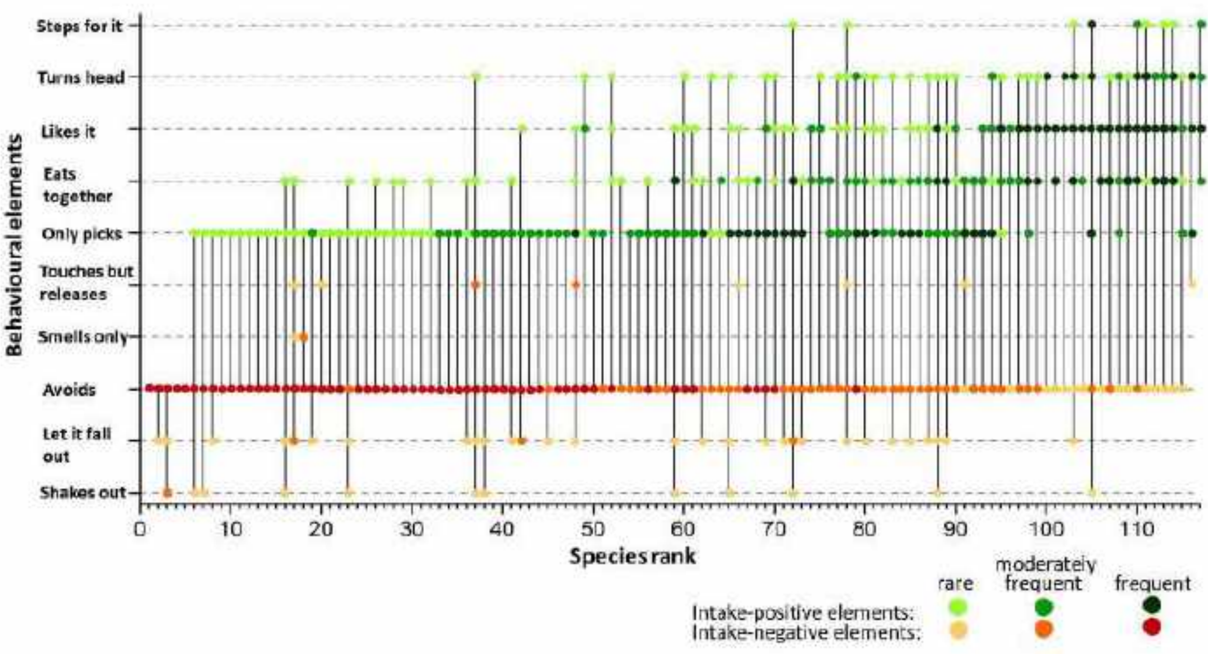

Fig. 1 Frequency of behavioural elements toward 117 plant species. Species were ordered from left to right according to their ranks based on their desirability index (proportion of intake-positive types, in %). Coloured dots indicate frequency of behavioural elements (from light (rare) to dark (frequent)). Dots of the same plant species are connected with a thin vertical line.

We also found that herders had broad knowledge of grazing desire and preference, and they consciously aimed to modify desire (selection behaviour on the short- and long-term) by slowing, stopping or redirecting the herd. Modifications were aimed at increasing grazing intensity in less desired patches and decreasing grazing selectivity in heterogenous swards. Many of these have significant conservation benefits (Table 1).

Table 1 Conservation relevant herding techniques of traditional herders in Central Europe used to control grazing behaviour, animal distribution, modify intake of livestock, change selectivity of grazing, and protect the forage resources on their pastures (frequency of application: ***: used often, *: used rarely).

Traditional herding techniques to control grazing behaviour	**Freq. of use**	**Conservation relevance of traditional herding techniques**
Attention to livestock, keep monitoring them for prompt and proper interventions with the least possible stress	***	Fine-tuned livestock-herder-pasture relation is the basis for proper management
Protecting the pasture from unnecessary disturbance and promoting regeneration after a grazing period	**	Herders consciously protect pasture vegetation according to their indicators
Designing daily 'menu' (sensu Meuret 1997, Meuret and Provenza 2015) along the grazing route (sequence of foods to maintain and boost appetite, and increase desirability of less preferred forage species)	**	Designed menus help utilize the pasture evenly, animals move less and fatten better (cf. profit) (leads to lower grazing pressure)
Letting them spread and graze calmly	***	Movement and trampling are decreased, smaller disturbance to breeding birds
Selecting an area to be grazed during its highest desirability status, depending on season and weather	**	Utilizes less preferred parts of pasture, often improving its forage quality
Block movement of the herd, or just slow them to get them satisfied with the less preferred forage of the patch, eat mixed forage	***	Less selective grazing results in more homogenous utilization and can prevent spread of pasture weeds
Targeted grazing of less-desired, less preferred forage species, improving pasture by grazing	***	Prevents accumulation of litter, and suppresses bushes and tall plants (like *Phragmites, Typha*)
Increasing willingness to graze less selectively and more intensively by shortening a meal from 4-5 to 1-1.5 hours	*	Less selective grazing (more homogenous utilization, and management of pasture weeds)
Move them faster (towards watering / resting places) to prevent excessive grazing trails	*	Too many grazing trails could cause degradation (spread of weeds)

In the second study we identified indicators herders use to understand the forage plant-livestock-herder relationship and to manage herds and pastures. The indicators of forage plants described botanical features, livestock behavior during grazing, and the impact of plants on livestock condition and health (Table 2). The indicators were used in context-specific management decisions, with a variety of objectives to optimize grazing. We identified ten global principles: 1) Livestock-centered perspective of forages; 2) Close monitoring and prediction of forage quantity and quality; 3) Use (targeted grazing) of plants with medicinal and good nutritional properties to improve livestock status and health; 4) Inner need for responsibility of the herder in modifying livestock's forage selection and intake; 5) The livestock is herded but to a certain degree it is allowed to play a decisive role in forage selection, place of grazing; 6) Using different livestock types to make use of various forage resources; 7) Making use of 'all' plant resources, through understanding and utilizing relative and changing palatability; 8-9) Adapting to changing forage availability by proper timing of grazing at multiple temporal, and at multiple spatial scales; and 10) Keep focusing on context-influenced change of forage preference and intake (Fig. 2).

Table 2 Indicators used by traditional herders and pastoralists to describe forage plants in different parts of the world, number of local indicators found, and number of countries where these indicators were documented (indicators were grouped, see bold categories).

Indicator	**No. of local indicators**	**No. of countries**
General valuation (good forage, bad forage)	590	12
Types of livestock that eats is	362	14
Nutritional value	244	17

Feeding behavior	2	1
Plant gender	1	1

Fig. 2 A) Hungarian herders point out "*I see the grass through the mouths of my animals*" (Molnár, 2017) which is similar to the observation of a French shepherd as described by Despret and Meuret (2016), that "*his* [the shepherd's] *fingers know and anticipate what the sheep's mouths know*". Both statements, though from herders situated in different countries and herding regions, accentuate the fact that herders' knowledge is partially gained through the close monitoring of the relationship between their animals and the forage. B) Hungarian herders say "*Tippan* (small tussocky *Festuca pseudovina* grass) *is the soul of the Hortobágy steppe!*", which is very close to the observation made by Mongolian herders living 6000 kilometers away who perceive that "*Botjul* (small tussocky *Festuca lenensis* grass) is the best grass that my livestock can find to feed on in Mongolia" (Gantuya et al. 2019, 2021).

Discussion and Conclusions

The traditional herd management practices, presented here, have significant conservation benefits, such as avoiding under- and overgrazing, and targeted removal of pasture weeds, litter and encroaching bushes, tall competitive plants and invasive species (Molnár et al. 2020, Sharifian et al. 2023). We argue that knowledge co-production with traditional herders who belong to another knowledge system could help connect isolated scientific disciplines especially if ecologists and rangeland scientists work closely with traditional herders, co-designing research projects and working together in data collection, analysis and interpretation. Stronger links between these disciplines could help develop evidence-based, specific conservation management practices while herders could contribute with their practical experiences and with real world testing of new management techniques (Molnár et al. 2016, Török et al. 2016, Vadász et al. 2016).

Although pastoralists vary greatly across the globe, the character and use of their traditional forage-related knowledge do seem to follow strikingly similar principles. Understanding these may help the local-to-global-level understanding of these locally specific systems, support bottom-up pastoral initiatives and discussions on sustainable land management, and help to develop locally relevant global and national policies.

Protection of sacred springs in South Australia's rangelands

Smith, A[1]; Gerlach, CA[1]; Warren, F[2]; Dadleh, K[2]; Booth, F[3]

[1]SA Arid Lands Landscape Board; [2]Dieri Aboriginal Corporation RNTBC, [3]Brook Pastoral Company South Australia.

Key words: partnerships, First Nations, mound springs protection

Abstract

Bubbling up from Australia's Great Artesian Basin, mound springs are unique lifelines across the rangelands and are of great ecological and cultural significance. For the Arabana and Dieri people, mound springs are central to their culture, and have sustained life in South Australia's desert lands for thousands of years. In partnership with volunteer group Friends of Mound Springs, Brook Pastoral Company, Dieri Aboriginal Corporation, and the South Australian Arid Lands Landscape Board (SAAL Board) a joint project has had positive outcomes for the culturally important Reedy Springs and St Mary's Pool on Murnpeowie Station on the Strzelecki Track.

Early engagement with all groups in a genuine partnership approach included involvement from initial ideas to co-design, planned works, site visits, and on-ground works. A 2.45 km fence was installed to protect the 42-hectare spring group, expanded to protect the springs as well as new cultural sites identified by Dieri people during site visits. In addition, fencing was also installed to manage vehicle access to a nearby waterhole. Knowledge has been shared on cultural and ecological values of the springs and ongoing monitoring will continue using the same collaborative approach.

Kokatha Aboriginal Corporation were contracted to complete the fencing works, further supporting First Nations employment and participation outcomes and a rich cross-cultural exchange. The Board is working with Arabana Rangers and Arabana Elders, along with FOMS, on opportunities for springs projects on their Country and will consult with other First Nations groups for new projects.

Introduction

South Australia's rangelands contain around 5000 mound springs, which are natural outlets for water from the Great Artesian Basin (GAB), one of the world's largest underground aquifers (Lewis et al. 2013). The mound springs have high ecological value, supporting unique and endemic plant and animal species, while also being culturally significant for Aboriginal people (Beasley-Hall et al. 2024, Hercus & Sutton, 1985). In South Australia, native title groups whose country covers the mound springs includes Arabana, Adnyamathanha, Yankunytjatjara/Antakarinja, Dieri, Yandruwandha/Yawarrawarrka, Wangkangurru/Yarluyandi, and Kokatha (National Native Title Tribunal, 2024).

For more than 40,000 years the springs have been vital sources of water in the arid environment, supporting periodical occupation during suitable conditions, and are linked to cultural stories, trade routes, ceremonies and sites of cultural significance (Brake et al. 2019). For example, for Arabana people, kutha ngarrawa (mound springs) are a central theme in their culture and the stories that connect Arabana people to their Country (Government of South Australia, 2017, Nursey-Bray & Arabana Aboriginal Corporation, 2015). Arabana are concerned about maintaining Wadlhu Ngurrku-ku (Healthy Country) with kutha ngarrawa providing water and resources, as well as being sites of ceremony and trade routes (Government of South Australia, 2017).

Following pastoral settlement in South Australia, the location of the springs shaped key infrastructure routes, such as the Overland Telegraph line and the Ghan railway (Harris 2002). Across the GAB, springs are under threat from reduced artesian pressures as a result of excess water extraction and uncontrolled bores, and due to physical disturbance of spring structure and dependent ecosystems through grazing, trampling and increased nutrients (Keppel 2022). In the South Australian rangelands, efforts are underway to mitigate these impacts and improve conservation and management of the springs, but meaningful engagement with First Nations, pastoral land holders, volunteer group, industry and government is required if springs management is to be successful.

Methods

In 2022, the SA Arid Lands Landscape Board (SAAL Board) received funding from the Lake Eyre Basin (LEB) Program (a federal program with funding from all LEB jurisdictions), and in 2023 from BHP mining company, with stipulation to deliver projects involving the protection of sites of ecological or cultural importance within the Lake Eyre Basin, which include mound springs.

Site selection - The need for multi-stakeholder involvement for springs management was identified early. Given the large number of springs in South Australia, the SAAL Board first approached Friends of Mound Springs (FOMS) for assistance in identifying suitable springs for protecting. FOMS is a volunteer group with members who have extensive knowledge of South Australian springs, their management history and condition, and have established relationships with First Nations groups.

After FOMS identified potential sites on Dieri and Arabana Country, consultation commenced with pastoral land holders and Dieri and Arabana, to establish which springs might be viable based on all groups' agreeance. The engagement process followed the guidelines in the SAAL Board's Communication and Engagement Strategy (SAAL Board, April 2022). Landholders were approached to gauge interest in participating in springs management and involved a site visit to confirm current conditions and the potential management options. While numerous sites were identified, the complexity of the site for management options (where stock water points, long-term management and spring topography were considered) and landholder interest in the project within the funding timeframe, meant the number of springs as option for the project, were reduced.

Following discussions with Dieri and Arabana, the scope of the project was refined to sites where fencing was deemed a suitable method for springs protection. Two sites were identified in further consultation with pastoral lease owner Brook Pastoral on its lease, Murnpeowie Station, on Dieri Country: Reedy Springs and St Mary's Pool. It is worth noting, that land managers need to approve a potential project, especially for infrastructure, prior to the final agreeance with the respective First Nations group.

The aims of the project were to manage non-native herbivore impacts to springs (Reedy Springs) using exclusion fencing and to manage visitor access to a nearby waterhole (St Mary's Pool) with fencing to prevent vehicle access. Furthermore, in addition to the fencing of Reedy Springs the land managers required an alternate water point to be identified, to reduce pressure on the fence from stock seeking water. Consequently, the project included installation of a new tank and trough, to be fed by new pipework connected to a bore 10km away.

Cultural Surveys and fence design **-** The main spring vents at the Reedy Spring group are situated in an area of relatively flat topography meaning fence installation is relatively simple. FOMS provided advice on fencing design given their years of fencing experience, with a design that allows for both kangaroo access and restricting non-native herbivores, while also considering soil conditions of the area.

Dieri completed a cultural heritage survey in October 2023 and the fencing boundary was expanded (from initial project design) to incorporate and protect the cultural and archaeological sites Dieri identified during the cultural survey.

Dieri were also concerned about visitor impacts and vehicle management options were discussed at St Mary's Pool with fence locations planned accordingly. On receiving heritage clearance approval from Dieri, a formal agreement was put in place with Brook Pastoral outlining the scope of work and responsibilities for ongoing maintenance.

Fencing - Dieri did not have the resources for completing the fencing, however, recommended other First Nations companies who may have the capacity. Subsequently, Kokatha Aboriginal Corporation were awarded the contract. To ensure the project met the expectations of all involved, a final site visit in May 2024 was conducted ahead of fencing work and any necessary adjustments were made. Representatives from SAAL, FOMS, Dieri, Brook Pastoral, and Kokatha attended.

At the time of fencing a vegetation survey was completed and georeferenced photos were taken to allow for comparisons in the future. The project was completed in early June 2024.

Results

The completed project saw 2.45 km of fencing erected to protect a 42-hectare area around Reedy Springs. The final fence design was a four strand barb wire fence, with rust resistant steel posts every six metres plus intermediate spacers, a main access gate and a spear gate to allow a point of exit for wondering stock. During the cultural heritage survey, cultural and archaeological sites were identified, and consequently, the fencing perimeter was expanded to include these areas. At St Mary's Pool the installation included a short fence consisting of polyethylene coated timber posts and chain gate to manage vehicle access.

The project involved three First Nations groups, one volunteer group (FOMS), a pastoral landholder (Brook Pastoral), multi-government funding, industry funding and the SA Arid Lands Landscape Board as the project facilitator and manager. A monitoring program is now in place for the site which includes fence and ecological (vegetation and water quality) inspections.

Discussion

First Nations involvement and engagement

The engagement process SAAL applied is an established way of doing business between the organisation and First Nations groups (SAAL Board, April 2022). The engagement approach, which sits between 'Collaborate' and 'Empower' on the IAP2 Spectrum of Public Participation (IAP2 2024), has additional benefits that extend beyond the delivery of an infrastructure project. Cross-cultural sharing between SAAL water project staff, FOMS, First Nations and the pastoral enterprise was valued by all involved and allowed everyone to gain an improved understanding of each other's context. While the project has contributed to the protection of a spring group from non-native animal access, of greater importance is the project has enabled First Nations groups to reconnect with the cultural connection they have with springs and be included in the decision making for protection.

Sharing project updates between all groups and collective on Country site visits kept the project on track and ensured the different groups' expectations were understood. Re-negotiating aspects of the project and reporting back to First Nation's Board Members to keep them informed was crucial to the project's success.

The timeline pressures that occur with external funding obligations can mean there isn't enough time for First Nations aspirations to be fully realised and considered in project planning. This is a matter that needs to be raised with funding bodies early, with extra flexibility sought, to shape the project as it evolves. Without this, there is risk that relationships, particularly between government and First Nations are damaged and projects may not reach completion, putting future projects at risk.

Springs Fencing

Reedy Springs is now one of the few springs in South Australia fenced for management purposes and it is worth considering the impact fencing will have on spring condition. It has been observed at other mound springs in South Australian where fencing or stock exclusion has occurred, that *Phragmites australis* has proliferated at the expense of other native flora (Gotch 2013) or has caused a reduction in open water (Harris 2020, Lewis & Packer 2020). However, this has occurred at springs where *Phragmites* was present at the time of fencing (e.g. Billa Kalina springs, The Fountain, Big Cadna-owie; Lewis & Packer 2020). Within the fenced area of Reedy Springs, no *Phragmites* was identified during site visits or prior to fencing and instead, the Springs are dominated by *Cyperus laevigatus* ('bore-drain sedge'). The risk, therefore, of *Phragmites* proliferation, following fencing and removal of grazing pressure is considered lower than at other springs where the species is already present, however regular monitoring of Reedy Springs will document any changes in vegetation composition and extent.

This project at Reedy Springs and St Mary's Pool resulted in renewed focus on springs management in South Australia's rangelands and has already allowed for further collaborative review, with Dieri and Arabana, of other springs with environmental and cultural significance that may benefit from active management. Ultimately this project resulted in strengthened relationships between government, First Nations groups, volunteers and pastoralists and has established a methodology, including the engagement process, that can be applied to the protection of other springs, or land management projects in region. The improved engagement process includes government and First Nations partnership at the very start of a program helping to ensure Traditional Owner guidance and cultural heritage are considered at early-stage project development.

Great Plains Grassland Extension Project: Tackling big conservation challenges through collaboration and cooperation

Baldwin, C[1]; Fogarty, D[2]; Hovick, T[2]; Treadwell, M[3]; Matzke, C[3]; Thompson, A[4]; Goodman, L[4]; Spackman, C[5]; Cram, D[5]; Overlin, A[6]; Bruegger, R[6]; Twidwell, D[7]; Scasta, D[8]; Beaver, J[9]; Bauman, P[10];

Key words: Woody encroachment; grassland ecosystem; collaborations

Abstract
Grassland biomes are often extensive, and challenges such as invasive species can span multiple jurisdictions and ownerships. How can conservation efforts be scaled up to make a meaningful difference on such a large landscape? When an entire biome is in distress, what can be done to address the conservation need? Woody encroachment is threatening the North American Great Plains ecosystem, replacing old-growth rangelands with a mix of undesirable brush and trees causing a loss of ecosystem services including habitat loss, soil hydrologic alterations, and drastic reductions in grazing capacity. Conservation efforts in the past have been fragmented between agencies and individual landowners without making impact at the needed scale and have failed to halt rangeland losses. New mapping tools allow more precise location of problem areas, and recent research provides a new approach to tackle the problem.

The Great Plains Grassland Extension Partnership offers an example of how conservation efforts can expand across a biome. Range management specialists within each state's Cooperative Extension System have united to coordinate outreach efforts to ranchers, share new management techniques, report success and challenges, and assist and coordinate other conservation agencies such as the Natural Resource Conservation Service and state wildlife agencies. A single message incorporating the urgent need and a new approach to tackling the woody encroachment problem at greater than the individual property size has provided hope for reversing the degradation of North American rangelands. The partnership allows each state to engage with local partners who can forward the same conservation message. Working together, there is hope for melting the "green glacier" of advancing woody encroachment covering the Great Plains (Engle et al. 2008).

Imperiled Biome
Grasslands cover up to 41% of the world's land area (Petermann and Buzhdygan, 2021) and support goods, services, and cultural values that to contribute to human well-being. Grasslands also provide food and fiber production and ecological and biological services including freshwater supply, biodiversity, cultural diversity, belowground carbon storage, and the regulation of natural hazards (Havstad et al., 2007).-Nearly half of global grasslands have been converted to other land cover types and remaining grasslands remain vulnerable to future loss.

The Great Plains of North America is among the largest temperate grasslands in the world. Woody plant encroachment is driving a biome-scale transition from grassland to woody dominance (Figure 1) (Briggs et al. 2005; Engle et al. 2008; Twidwell et al. 2022; Morford et al. 2022). Causes include a lack of prescribed fire (Twidwell et al. 2013), introduction of seed sources (Johnson 1923), small scale approachs to control (Fogarty et al. 2022), and a carbon-enriched atmosphere (Blair et al 2014). Woody encroachment includes both brush and tree species. Junipers, especially eastern redcedar (*Juniperus virginiana*), while native, have been continually planted where they were historically scarce (Ganguli et al., 2008; and have rapidly spread.

Woody encroachment in the Great Plains can lead to a potential 75% reduction in rangeland production and escalating costs of brush management that can easily exceed annual revenues generated from rangelands (Fuhlendorf et al. 2008; Natural Resources Conservation Service 2021). These losses are resulting in a decline in ecosystem function and services that benefit communities in the Great Plains and throughout North America (Twidwell et al. 2013).

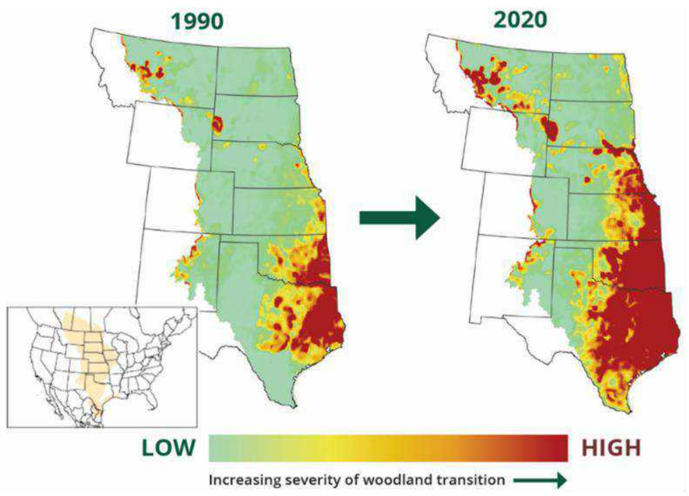

Figure 1. Woody plant encroachment is driving a large-scale transition from grassland (in green) to woody dominance (in red) in Great Plains grasslands from 1990-2020. Adapted from Fogarty et al. (2023).

Past efforts to control and reduce woody encroachment in the Great Plains have relied heavily on brush management and have been unable to halt the loss of grasslands at large scales (Archer et al. 2011; Rheinhardt et al. 2021). Several challenges have contributed to this outcome: 1) brush management is a reactive conservation practice that consists of woody plant removal in areas that have already experienced losses due to woody encroachment. An over reliance on this expensive practice has limited opportunities for more cost-effective and proactive approaches (Twidwell et al. 2021). 2) Follow-up management to address the rapid reinvasion of woody plants after mechanical removal is often lacking and results in short-lived management treatments (Fogarty et al., 2021; Scholtz et al. 2021). And 3) management treatments are often scattered across the landscape and lack spatial arrangement needed to benefit the broader landscape (Twidwell et al. 2021). There is a need for a more proactive and spatially targeted approach for reducing woody encroachment that addresses the underlying risks that drive woody encroachment (Twidwell et al. 2021).

New approaches for reducing woody encroachment

New approaches for reducing woody encroachment were designed to overcome key weaknesses of past approaches and better allow practitioners to scale up management over time (Twidwell et al. 2021). Management guidelines were built around a framework for reducing the risk of encroachment in grasslands. Management guidelines were then designed to 1) prevent risk from increasing in intact grasslands and 2) reduce the risk of encroachment by minimizing grassland exposure and/or sensitivity (Fogarty et al. 2023). For instance, prescribed fire can be used to manage the dispersal and recruitment stage of woody encroachment and prevent the loss of intact grasslands (Figure 2). In addition, restoration actions can be used to remove seed-producing woody plants, deplete the seedbank, and expand the extent of intact grasslands over time.

The workshop brought together scientists, extension specialists, and conservation practitioners from across the Great Plains region to improve the planning, design, and delivery of conservation investments. Ultimately, the workshop led to the development of an 85-page pocket guide (Fogarty et al. 2023) that serves as a resource for training the rangeland workforce on how to recognize and reduce grassland vulnerability to woody plant encroachment across a range of landscape contexts. With nearly 25,000 copies distributed in the first year of publication, the pocket guide has supported local field trainings across Great Plains states as part of efforts to scale up the implementation of new management guidelines (Figure 3).

The Great Plains Grasslands Extension Partnership offers an example of how regional partnerships in extension and outreach can be created to address large-scale threats. Next steps include the formalization of training and professional development opportunities through extension- and agency-sponsored education programs. The Extension Partnership has supported an unprecedented level of collaboration among scientists, extension specialists, and practitioners to address the biome threat of woody encroachment.

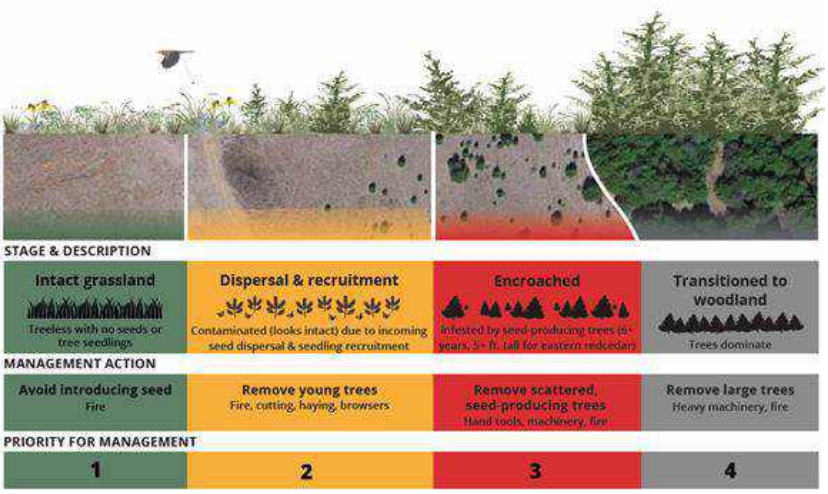

Figure 2. New management guidelines prioritize proactive management to prevent encroachment of intact grasslands and expand them over time through targeted management of encroached rangelands (Twidwell et al. 2021).

Figure 3. The Great Plains Grasslands Extension Partnership has supported a regional extension and outreach campaign to speed up the adoption of new management guidelines for reducing woody encroachment.

Key words: IYRP; soccer; digital platforms; outreach

Abstract

Overall, our global population has a very limited knowledge of rangeland ecosystems and the communities who most depend on them, despite the fact that rangelands comprise over half of the world's land area and supply vital ecosystem services such as food, fiber, and recreation. Therefore, how can we increase public understanding about rangeland systems to heighten awareness and improve rangeland policies and stewardship? The International Year of Rangelands and Pastoralists (IYRP) will occur in 2026 as approved by the United Nations General Assembly in 2022. Many events are planned to celebrate the IYRP, with a major emphasis on expanding global awareness. The FIFA World Cup is also happening in 2026, which after the Summer Olympics is one of the greatest world sporting events. This sporting event is held once every four years. The most recent FIFA World Cup was hosted by Qatar and was watched by over five billion people (61% of the global human population). For the first time in history, the 2026 FIFA World Cup will be hosted by multiple nations: the United States, Mexico, and Canada. Can the IYRP leverage attention for the 2026 FIFA World Cup to boost public appreciation for global rangelands and pastoralism? If so, how might this be achieved? Social media offers several tools and opportunities that could be useful to this end. In the lead-up to the games, for example, creative posts of rangeland residents playing soccer on unique, beautiful, and remote landscapes combined with targeted messaging could attract a large audience. This poster will explore various social media options, tentative frameworks or approaches, and the general feasibility for achieving impact. Partnerships with groups such as the IYRP Pastoralist Youth Working Group - distributed across 11 regions worldwide- could help provide raw material in the form of videos, photos, text, and artwork.

Introduction

According to the United Nations Environment Programme (UNEP) (2014), rangelands occupy 54% of all land on Earth, and at least 30% of land in the United States is rangelands (NRCS, 2024). Rangelands are home to an estimated 200 million people worldwide, which represent approximately 2.5% of the world population. Nevertheless, people often do not know or recognize the importance of rangelands in their lives. In North

America, rangelands are particularly important for livestock and fiber production, wildlife habitat, and recreational activities among other things. The mission of the International Year of Rangelands and Pastoralists (IYRP 2026) is to promote an understanding and appreciation of rangelands around the world, the people who manage them, and their contributions to all communities.

The objective of this project is to try to use social media as a platform to bring awareness to the general public as to what rangelands and pastoralists are. As of October 2024, 63.8% of the global population uses social media (DataReportal, 2024). Furthermore, 94.5% of the world's internet operators use social media at least once a month and the typical social user spends more than 2 hours per day on social media (Figure 1). These statistics show that social media could be a great way to reach a larger audience for the IYRP 2026. Our project will also take advantage of the FIFA World Cup 2026 happening in the United States, Canada and Mexico. The 2022 FIFA World Cup was able to engage over five billion people; which represents roughly 61% of the world population. Using this attractive event, which is watched and followed by a very large portion of the general public could be an effective way to talk about rangelands and pastoralists to people who might not be familiar with rangelands and the people working those lands.

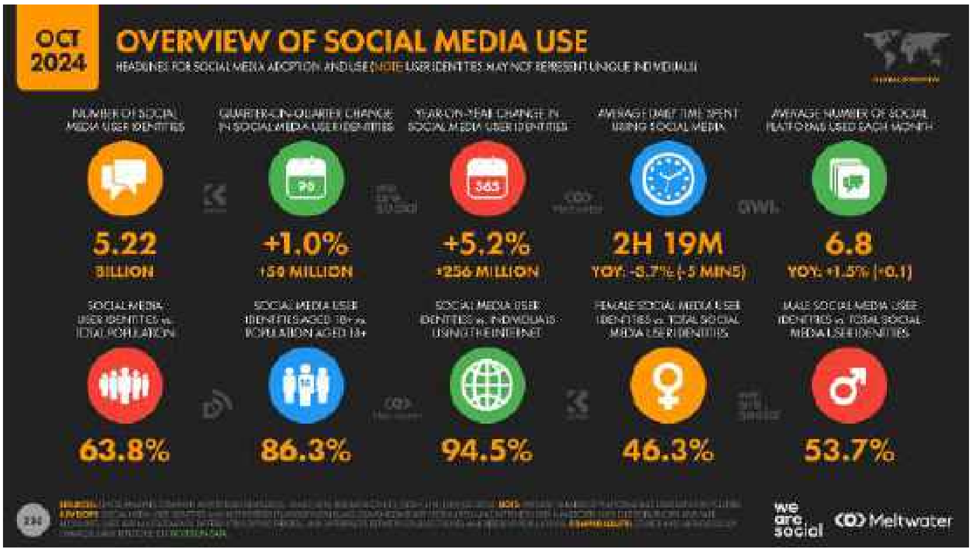

Figure 1: Overview of Social Media Use (DataReportal, 2024)

Methods

As of December 2024, our project is in the preliminary stage of development. Currently, the project has no funding. However, the core team is working on three main general ideas. The project was presented for the first time at the Society for Range Management (SRM) Annual Meeting in Spokane, Washington in February 2025. At this international meeting, we received feedback from rangeland scientists and professionals on our three main ideas to help us move forward with this project. The audience was very receptive and provided useful advice. We also used this opportunity to collect contact information of people who could provide photos and/or videos for our social media platforms. Our project is divided in two major components, namely: the FIFA World Cup Outreach and the Social Media Outreach.

There are 11 IYRP 2026 regions around the world (i.e. the Artic, Australia/Oceania, Central Asia & Mongolia, East Asia, Eastern & Southern Africa, Europe, North Africa & Middle East, North America, South America, South Asia, and West & Central Africa). Our plan is to represent and engage each region as much as we can. On our team, we have representants of the IYRP 2026 Pastoralist Youth Forum which will also help us engage youth in this outreach project.

FIFA World Cup Outreach

The final product for the 2026 FIFA World Cup Outreach may be about 10 videos (if possible) to be launched from March 2026 to July 2026 on social media. There will be two videos a month that will be viewed before the FIFA World Cup and during the sporting event. We will collect footage from all around the world of pastoralists playing soccer on rangelands. As a result, we will be able to have a diversity of footage which shows the variety of pastoralists and rangelands worldwide. Some of these videos will showcase traditional clothing worn by pastoralists around the world to illustrate material culture. In the videos, a soccer ball will roll through the different landscapes where pastoralists pass it to each other across the screen to establish connectivity among the different rangelands. For each video, there will be music, some text regarding facts about pastoralists and rangelands, and the IYRP 2026 logo and website. In order to simplify the editing work for this project as it is solely volunteer based, we have a demonstration production video to standardize approaches and illustrate filming recommendations. We will identify a network of people in the field who would be in charge of collecting footage for each IYRP region.

Social Media Outreach

For this part, we have two ideas. First, we will create monthly short videos based on the IYRP 2026 monthly themes (Figure 2). These short videos will be a photo montage of all of the 11 IYRP 2026 regions around the world. For each video, we will have photos, music, some text regarding facts about pastoralists and rangelands, and the IYRP 2026 logo and website. We will also have a rolling credit page at the end to thank each photographer for their contributions to the project. We plan to have the same structure for each video to provide a consistent message for the general public. Second, we will do a weekly "*Find the IYRP 2026 logo in this photo, and learn an interesting fact about rangelands and pastoralists around the world! #IYRP2026 #SRM*" on social media (Figure 3). This will allow us to share 52 photos over the year 2026 representing rangelands and pastoralists worldwide. We will post a photo on social media every Tuesday with a hidden IYRP 2026 logo, and on Fridays, we would announce where the logo was hidden and will give an explanation of what is shown in the photo. As we know, photos are a very powerful way of communicating! All of our social media outreach will be in English, Spanish and French.

Figure 2: IYRP Themes

Figure 3: Example of the Find the IYRP logo social media outreach idea

Timeline

The first half of 2025 will be focused on collecting footage (videos and photos) from partners and colleagues. The second half of 2025 will be focused on video and photo production. The year 2026 will be focused on distribution (Figure 4).

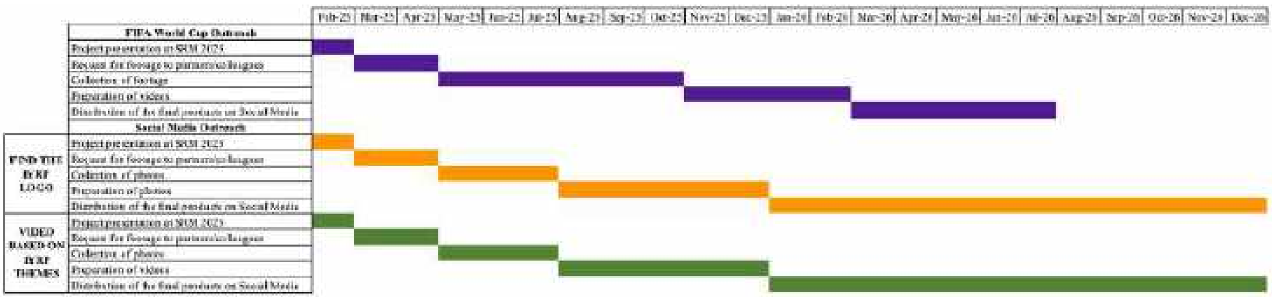

Figure 4: Outreach Projects Timeline

Overall, due to the statistics on the world's top social media platforms, our focus will be on Facebook, YouTube and Instagram (Figure 5; DataReportal, 2024)

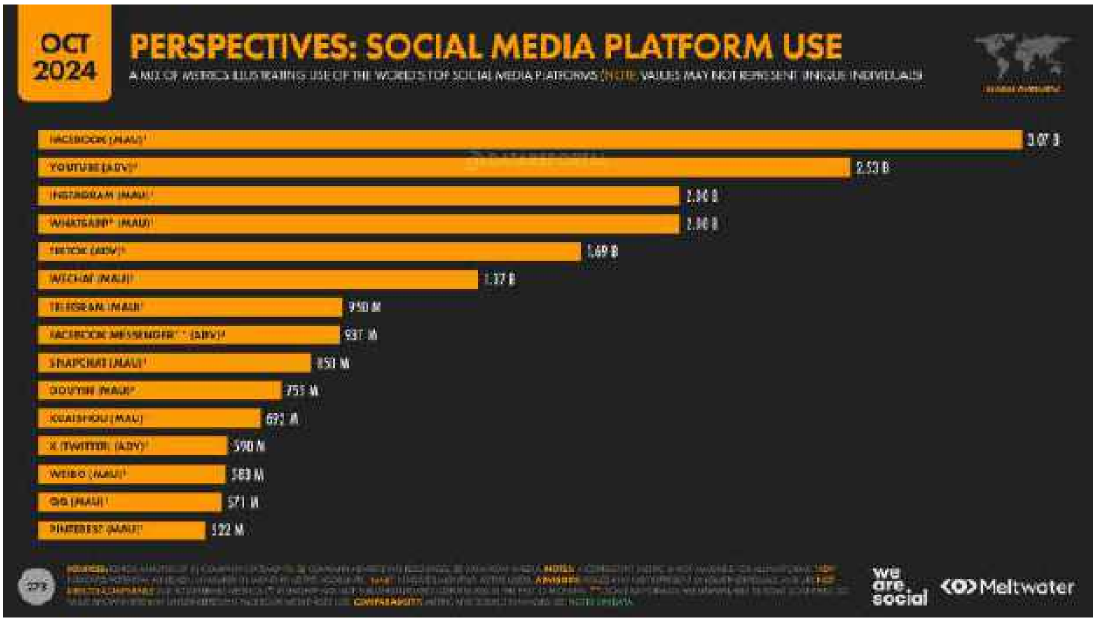

Figure 5: Social Media Platform Use (DataReportal, 2024)

Results

Because this project is still in a preliminary phase, we do not have any results to share yet. However, we plan to collect engagement data on the different social media platforms in order to learn more about the impacts of the outreach project. The data collected include, but are not limited to views, likes, comments, reactions, and shares.

Discussion/Conclusions/Implications

Because this project is still in a preliminary phase, we cannot yet discuss results or project impacts. However, our objective is to bring awareness about rangelands and pastoralists to the general public during the International Year of Rangelands and Pastoralists in 2026. We anticipate to achieve this with this project.

We received useful feedback on our ideas during the Society for Range Management Conference in February 2025. We submitted a funding request (pending) to the Society for Range Management to hire a professional editor for the videos related to the FIFA World Cup. We believe that our ideas will evolve with time and that new perspectives might emerge in the next few months. Other ideas are already emerging. For example, we may hold a mini-competition for the best soccer video with a soccer ball with the IYRP logo as a prize. This and other ideas may grow if funding sources are located.

Collaborative approach to grazing management

Participatory rangeland management (PRM): from concept to continental scaling

Key words: Participatory rangeland management, pastoralism, restoration, planning, community

Abstract

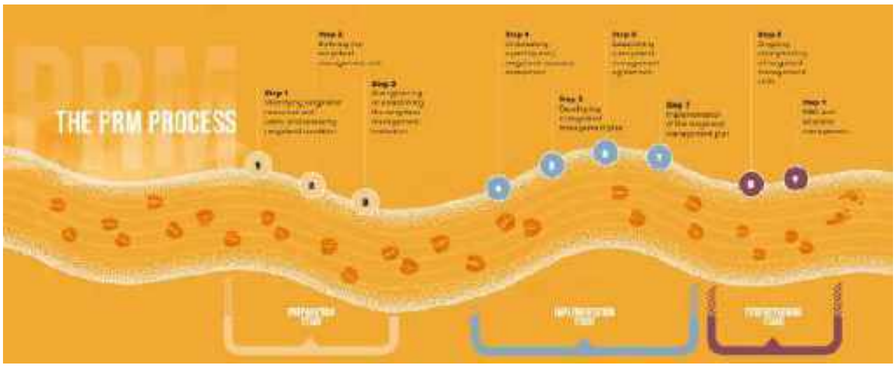
Participatory rangeland management (PRM) is a step-by-step process that builds the capacities of pastoralist communities to improve the management, governance and restoration of their land and resources. It seeks to address the challenges that pastoral communities across Africa face including a lack of tenure security with an increasingly degrading resource base as pressures on land grow. Introduced in 2010, it is now being implemented across more than 2 million hectares in East Africa. Three impact pathways were followed to reach this point – developing and piloting PRM, building capacities to implement PRM, and influencing a more enabling policy environment. However, though PRM in name can be easily scaled in terms of coverage, greater attention must be given to maintaining its core principles and deepening community engagement and capacities. It requires a significant investment from all involved including sufficient time and funding to move at a pace that allows for capacity building of communities to *lead* the process, co-develop solutions and support policy and legislation improvements.

Introduction

Pastoral communities across Africa face the ongoing challenge of a lack of tenure security with an increasingly degrading resource base as pressures on land grow. In 2010 n an attempt was made to reverse this situation; participatory rangeland management (PRM) was developed in Ethiopia drawing from the experiences of participatory *forest* management, adapted to a rangeland context (Flintan and Cullis 2010).

Following the introductory guidelines PRM was piloted at different scales (local/village and landscape) and later expanded across a million hectares. Evaluations highlighted its' initial impact and potential for strengthening good governance, improving rangeland health and productivity, reducing land use conflicts and benefiting local communities – both men and women (Flintan et al. 2019; Flintan and Eba 2023).

In 2019 PRM was introduced to Kenya and Tanzania by an EU-funded project implemented by local NGOs (namely RECONCILE, Tanzania Natural Resource Forum and KINNAPA) with technical support provided by ILRI. An independent assessment of this implementation highlighted important gains in rangeland management, livestock productivity and women's participation (Waweru et al 2021). More recently, ILRI and partners have supported its application in additional locations and as part of broader development processes such as within One Health and introducing gender transformation, climate security, peacebuilding, livelihood development, and rangeland restoration.



Today PRM is being implemented across more than 3 million hectares in Ethiopia, Kenya and Tanzania, with almost two-thirds of this being supported by ILRI (Flintan et al, 2025). A multistakeholder PRM scaling readiness workshop in Addis Ababa in mid-2024 set an ambitious target of all of Ethiopia's pastoral areas under PRM by 2034. Furthermore, the Intergovernmental Authority for Development (IGAD) Centre for Pastoral Areas and Livestock Development (ICPALD) and ILRI co-developed a manual on PRM (ICPALD 2024), with the aim of scaling across the IGAD region over the coming years. Additionally, ILRI is supporting the development and implementation of large-scale investments in PRM including an EU-funded Eastern/Horn of Africa project and a SDC-funded East Africa regional project.

There is a clear commitment to PRM in the East Africa region. There are also opportunities to expand to other countries e.g., Mali, Senegal (Flintan et al. 2022), Somalia (Flintan 2024) and Tunisia (Sghaier and Frija *forthcoming*). However, scaling PRM has challenges. This paper reflects on these, the impact pathways followed to reach this point, and what is being done to strengthen the approach and scale it.

Outcome impact pathways
i) Developing and piloting PRM

PRM is a process that can take many years to achieve and does not work well in short-lived project-oriented contexts. It requires long-term and consistent funding over at least five years as well as firm commitment from communities and supporting stakeholders. It has proved important to make this clear from the outset, and where possible offer shorter-term incentives such as livelihood-focused activities and learning visits alongside PRM establishment.

It has also proved important to develop and promote core PRM principles, which sets it aside from other community-based natural resource management approaches. First and foremost PRM is community-led. Having participatory rangeland resource mapping as the first step in the process has proved important for community leadership (Irwin et al 2015) Also PRM requires working at different scales – at the broader rangeland unit and at household cluster or village level with well-established linkages between.

Gender equity and social inclusion are also important principles. Though the community needs to be responsible for the rangeland management institution there is opportunity to influence its membership to be more inclusive (Bullock et al 2022). Gender transformative tools and approaches appropriate for collective societies to influence greater equity e.g. community conversations (Bullock 2024) and women's leadership forums (Dungumaro and Mkami 2019) can be introduced. PRM can be an important vehicle for building collectivity and such as peacebuilding – however, this has proved challenging and a recent study on the impact of PRM on collectivity showed little impact (Ng'ang'a et al 2024).

ii) Building capacities to implement PRM

Implementing PRM requires new skills and capacities as well as a change of mind-set i.e. that we 'outsiders' are facilitators of PRM and not drivers or leaders. The community also requires capacity building, and particularly where traditional institutions and practices have broken down. An institution capacity assessment is undertaken to understand needs.

New challenges may be faced that require co-developed solutions e.g. dealing with invasive species and restoring lands. Building up a toolbox of training resources targeting different stakeholders has taken time, particular as stakeholders work at different levels and with different priorities. In 2024 ILRI supported ICPALD to produce a manual on PRM for practitioners (ICPALD 2024).

iii) Influencing a more enabling policy environment

A process such as PRM requires an enabling policy environment and this has proved elusive. In Ethiopia the policy environment was neglected during initial piloting, and still there is no policy and legislation that supports PRM in same way policy and legislation on participatory forest management supports community rights to forests. However, steps have been made towards this through CARE Ethiopia establishing government-led regional PRM technical working groups, as well as the integration of PRM into government-led projects such as the Lowlands Livelihood Resilience Project Phase Two. And in Kenya working at county level (rather than national) has proved productive (Carleton and Flintan 2023).

Concluding remarks

Participatory rangeland management has significant potential for strengthening rangeland management and governance building on what communities are already doing, their knowledge and their institutions where functioning well. However, to be successful, it requires a significant investment from all involved including sufficient time and funding to move at a pace that allows for the capacity building of communities to lead the process and to build government support. The development and implementation of PRM by ILRI and partners has had positive results, however there is still much to improve and work on both in terms of deepening PRM implementation and getting scaling right.

Keywords: Working landscape; societal benefits; temporal and spatial scale

Abstract

Rangelands can serve as nature-based solutions to climate and biodiversity crises by sequestering and storing carbon and providing habitat for multiple species. Since rangeland systems are complex, inherently variable, and are facing high rates of change, prescriptive or standardized management practices cannot reliably produce desired benefits. Since 2014, the South of the Divide Conservation Action Program Inc. (SODCAP) has collaborated with rangeland managers in Saskatchewan, Canada, employing a participatory, outcome-based approach to enhance ecosystem health and wildlife benefits in a livestock production context. SODCAP's ongoing Living Lab - Central Prairies (LL-CP) project engages agricultural land managers, researchers, and other stakeholders, using a producer centric approach, to identify characteristics of grazing management systems that can reliably produce needed benefits, including carbon storage and biodiversity. Work to date indicates that a Diverse Adaptive Landscape-Livestock Interaction (DALLI) approach to grazing management is used by local ranchers to ensure that desired benefits are produced over time. DALLI managers dynamically adjust grazing strategies and tools across spatial and temporal scales to distribute livestock impacts throughout landscapes, leveraging techniques like animal herding, strategic water and mineral placement, flexible fencing, and incorporation of diverse perennial and annual land use types within grazing systems. Management responds to and promotes ecosystem heterogeneity, producing a shifting mosaic of impacts, which supports system resilience and biodiversity. Interviews with ranchers who use this approach underscore how diverse factors, such as climate conditions, economic viability, and community well-being, shape management decisions and outcomes. LL-CP's ongoing data collection on soil carbon, greenhouse gas emissions, plant biomass, diversity, nutrient quality, and socioeconomic factors will help to quantify the benefits of DALLI grazing management. This work will help validate the potential of diverse, adaptive grazing strategies to promote sustainable rangeland management amidst dynamic environmental challenges.

Introduction

Rangelands can serve as nature-based solutions – helping curb both the climate and biodiversity crises – but are threatened by conversion, degradation, and climate change (UNCCD 2024). Commonly recommended management practices do not perform reliably in all contexts (Buma et al. 2024) and can negatively affect other important values, like species diversity (Grenke et al. 2020). To better ensure that rangelands provide needed benefits over the long term, solutions must reflect the inherent complexity of rangeland systems

(Walker 2020) and should be defined in collaboration with knowledgeable local rangeland managers (Teague and Kreuter 2020).

Rangelands are complex social-ecological systems, with unpredictable outcomes due to interactions and interdependence of their parts. Grazers interact with variable topography, soils, plants, and other ecosystem features, creating heterogeneity, which in turn influences other ecosystem processes (Fuhlendorf et al. 2017). Managers weigh diverse priorities and select different management approaches depending on their motivations and practical considerations. Conventional rangeland management has sought to reduce this complexity, prescribing practices that discourage or prevent selective grazing, to make ecosystems more efficient and predictable. This approach assumes that livestock production is the primary goal, and that uniform use of homogenized landscapes will maximize livestock production. However, the anticipated benefits do not always materialize (Briske et al. 2008), possibly because heterogeneity is important for the functioning of rangeland ecosystems (Adler et al. 2001).

Beneficial grazing management encompasses more than just production and should support healthy ecological functioning and long-term resilience of rangeland systems. To achieve this, management must be robust to extreme and highly variable climates, including excess moisture and drought; must address enduring impacts of historical land management; and must be capable of adapting to relevant environmental, economic and social changes, all while ensuring the production of multiple benefits. Operations should be financially viable, but short-term economic gains should not hurt long-term sustainability or involve trade-offs with crucial benefits such as biodiversity or carbon storage. Given that there are still many unknowns about the dynamics of rangeland systems, and increasing uncertainty about how these systems will function in the future, there is no one-size-fits-all definition of beneficial grazing management. Certainly, adaptive management is key. Briske (2017) further suggests that collaborative learning and collective action by diverse stakeholders is required to produce knowledge, increase adaptive capacity, and maintain resilience. Similarly, Teague and Kreuter (2020) advocate for researchers working directly with innovative rangeland managers to better understand, quantify and communicate how they secure beneficial outcomes.

In Canada, where most prairie ecosystems have been converted to annual cropland, rangelands are crucial reservoirs of diverse cultural, social and ecological benefits. Some prairie rangeland managers and institutions have been especially proactive in ensuring these benefits are produced, and that managers are recognized for their efforts. At the same time, policy makers are seeking input on what constitutes beneficial grazing management in various regions across Canada (Government of Canada 2024). This paper, utilizing the existing network of managers and researchers aims to describe a management approach.

Methods

The South of the Divide Conservation Action Program Inc. collaborates with rangeland managers in Canada's Prairie Ecozone, employing a participatory, outcome-based approach to enhance ecosystem health. Since 2014, we have formed dozens of land management agreements aimed at improving outcomes for wildlife, soils and vegetation within a livestock production context. Most agreements define target outcomes that managers aim to achieve, but do not prescribe methods by which to achieve them. In 2022, we engaged producers and other collaborators in a living lab project (McPhee et al. 2021), in which diverse participants work together to identify innovative pathways for creating agri-environmental benefits in working prairie agricultural landscapes. Living Lab – Central Prairies (LL-CP) has undertaken five formal co-development sessions focused on grazing management to date, with 39 producers engaging with researchers and other stakeholders through to facilitated sessions and iterative group discussions. Participants share and discuss observations and preliminary results concerning soil carbon, biodiversity, economics and more, and how these outcomes are affected by management. LL-CP researchers have also conducted semi-structured interviews with core participating producers (n=22) to better understand the practices managers undertake and why. These producers can all be considered rangeland managers.

The rangeland managers contributing to results operate diverse operation types – including ranches, farms, and community pastures – using management units that range from a few hundred hectares to 1000 hectares in size. Their operations are distributed across the three main soil zones of southern Saskatchewan (black, dark brown and brown chernozemic soils). This also represents a moisture gradient from mesic (black) to xeric (brown).

Observations

To address complex intertwined goals and desired outcomes, managers are utilizing a newly defined Diverse Adaptive Landscape-Livestock Interaction (DALLI) approach to grazing management. The approach is so named because managers dynamically adjust grazing strategies and tools across spatial and temporal scales to distribute livestock impacts throughout landscapes, taking advantage of animal behaviours interacting with natural variability to create heterogeneity. Managers monitor and respond to heterogeneous impacts in real time, leveraging diverse tools and techniques like animal herding, strategic water and mineral placement, flexible fencing, and incorporation of diverse perennial and annual land use types within their grazing systems,

Table 1: Comparison of characteristics of conventional grazing management approaches for the Northern Great Plains (NGP) region, Adaptive Multi-Paddock (AMP) and Diverse Adaptive Landscape-Livestock Interaction (DALLI).

Grazing management characteristics	Conventional approaches for NGP region	Adaptive Multi-Paddock (AMP)	Diverse Adaptive Landscape-Livestock Interaction (DALLI)
Paradigm	Homogeneity/ efficiency-based	Homogeneity/ efficiency-based	Heterogeneity/ system-based
Primary goal	Production without degradation of forage resources	Production with enhancement of soil health	Optimization of multiple social-ecological values
Mode of success	Prescribed practices	Prescribed practices	Defined outcomes
Rest periods	Incidental; in avoided areas	Prioritized; planned, post-disturbance (for recovery of desired species)	Prioritized, planned and *ad hoc*; pre- and post-disturbance (for stockpiling and plant community recovery)
Grazing periods	Long; planned based on expected forage supply	Short; planned based on expected forage supply, with some flexibility in response to actual supply	Variable; planned based on expected forage supply, with high flexibility in response to actual supply
Stocking rate	Low-Moderate	Moderate-High	Variable
Stock density	Low	High	Variable
Season of use and rest	Fixed	Fixed-Variable	Variable
Pattern of grazing impacts	Pasture-scale; fixed gradients of use, persisting and being reinforced over time	Operation-scale; uniform impacts, being reached sequentially, paddock by paddock	Patch- to landscape-scale; variable, shifting in space and time

Within the DALLI approach to grazing management, livestock interact with landscape features to create a shifting mosaic of disturbance that responds to, interacts with, and modifies preexisting variability in soil, water, vegetation, and other biotic and abiotic site characteristics, at multiple spatial and temporal scales. Managers desire to maintain actively growing and residual plant cover within an acceptable range of variability (which varies with site and vegetation characteristics) and to avoid livestock use of grazed patches and plant communities until adequate recovery has occurred. To ensure these outcomes are met, they carefully observe actual conditions, and adjust specific actions as required. A key element is rest, especially of native pastures, as a stockpile for future use and as a means of "drought proofing".

Iterative monitoring and adaptive management are utilized to meet desired management outcomes. Managers' attentiveness and flexibility allows them to layer new values and priorities on existing operational plans; to show leadership in how to achieve desired outcomes; and to seize new opportunities.

Achieving target outcomes often requires management to influence multiple responses – such as plant architecture, plant density, plant community composition – which may vary spatially and temporally, and which in turn influence multiple other ecosystem components (e.g., insect and bird communities; forage and livestock production).

Rangeland managers are spread over many differing landscapes and follow many different business models. As a result, there is no single solution to the desired multilayered environmental and socioeconomic outcomes. Interviews to identify key elements of DALLI with ranchers who use this approach underscore how diverse factors, such as climate conditions, economic viability, and community well-being, shape management decisions and outcomes. DALLI managers generally value long-term – often multi-generational – productivity of the working landscapes.

When compared to conventional approaches, and to Adaptive Multi-Paddock Grazing, a beneficial grazing management practice proposed by Teague et al. (2013), the DALLI management emphasizes heterogeneity and the prioritization of multiple social-ecological values (Table 1). DALLI management aims achieve defined outcomes, using variable grazing and rest periods, stocking rates, stock densities, and season of use to create a pattern of grazing impacts that shifts in space and time.

Discussion

The DALLI approach is a product of complex systems and is well-suited for undertaking management of rangeland systems characterized by high uncertainty. DALLI managers emphasize and enact adaptive management throughout their operations, dynamically adjusting grazing strategies and tools in response to emerging characteristics of the systems in which they operate. Managers are themselves a key component of the grazing system, with actions taken contributing and responding to emerging characteristics of the system. Specifically, management responds to and promotes ecosystem heterogeneity, producing a shifting mosaic of impacts, which supports system resilience and biodiversity. Since the DALLI approach inherently prioritizes multiple benefits, managers are well positioned to layer new values and priorities onto their operations, address challenges, and seize new opportunities when social and environmental conditions change. These features may make DALLI a particularly effective approach to beneficial grazing management in the Canadian prairies and beyond.

Ongoing data collection and analysis on soil carbon, greenhouse gas emissions, plant biomass, diversity, nutrient quality, and socioeconomic factors within the LL-CP project will help to quantify the benefits of DALLI grazing management. This work will help validate the potential of diverse, adaptive grazing strategies to promote sustainable rangeland management amidst dynamic environmental challenges. Together, biophysical and economic findings, qualitative analyses of social science interviews and ongoing co-development with participating rangeland managers will help explain how and why DALLI approaches can help ensure needed benefits are produced over the long term.

Conclusion

Around the world, rangeland managers are helping to ensure long-term productivity of these working landscapes, while recognizing and advocate for recognition of multiple values produced. They are a vital part of rangeland systems, and their attentiveness and flexible approaches are key to ensuring their success. As the production of social and ecological benefits from rangelands grows in profile and importance, and uncertainty about future conditions rises, we must continue to support, learn from, and communicate the successful approaches of knowledgeable and effective managers – including DALLI managers in the Canadian prairies – to understand and define locally appropriate approaches to beneficial grazing management.

Key words: farmer-centric; collaboration; co-design; rangelands; producer-led research

Abstract

The value of conducting research with multidisciplinary and inter-disciplinary teams, involving both researchers and practitioners to develop problem-orientated and solution-focussed research is well recognised. 'Rangelands Living Skin' was a five-year project linking producers, scientists, education and extension agencies, commercial carbon companies and communications experts to evaluate cost-effective practices that focused on regenerating the New South Wales (NSW) rangelands in Australia, and supporting productive, profitable and sustainable businesses. The project brought together 12 project partners, plus additional expert consultants. The project aimed to create an evidence-base and build capacity for widespread adoption of practices that benefit soil, plants, animals and people – the living skin of the rangelands. Collaboration and co-design were at the core of the project, which took a farmer-centric approach. Producers from four grazing enterprises in western NSW were involved in all aspects of project design and delivery. An additional 26 producers were also signed up as 'observers', attending project events, collecting data across their own properties and creating a community of like-minded pastoralists in western NSW. Benefits of this approach included improving the breadth, robustness and relevance of the scientific research, bringing together diverse experience and perspectives, connecting stakeholders and increasing the project reach, producer engagement and participation. However, this approach was not without challenges, including increasing project complexity and scope creep, managing varying expectations of different partners, maintaining engagement and balancing the need for scientific design and rigor with practicalities of producer priorities and the environmental context. Key findings and recommendations from the Rangeland Living Skin project in undertaking collaborative, co-designed research for successful producer engagement, industry collaboration and adoption of research outcomes in rangeland grazing systems are discussed.

Introduction

The rangelands of New South Wales (NSW), Australia consist primarily of privately managed extensive grazing enterprises on native grass and shrublands that receive on average less than 500 mm rainfall per year. Historic overgrazing, uncontrolled total grazing pressure (TGP) and drought have collectively led to widespread soil degradation, erosion, loss of perennial grasses, poor landscape function and a loss of productivity across the region (McKeon et al. 2004). These drivers reduce community, business and landscape resilience, and as result, producers are looking for cost effective solutions to regenerate their resource base and remain viable into the future. Rangelands Living Skin (RLS) was a five-year project linking producers, scientists, education and extension agencies, commercial carbon companies and communications professionals to explore and evaluate cost-effective practices that focused on regenerating the NSW rangelands and provide support to enable livestock businesses to be productive, profitable and sustainable. The project aimed to create an evidence-base and build capacity for widespread adoption of practices that benefit soil, plants, animals and people – the living skin of the rangelands.

The value of conducting co-designed collaborative research, involving both research and practitioners to develop problem-orientated and solution-focussed research is well recognised (Mauser et al. 2013, Moser 2016). It has been a successful approach in projects in Australia (e.g., Price & Hacker 2009, Bridle & Price 2009) and internationally (e.g., Wilmer et al. 2022), increasing stakeholder engagement and connecting a diverse network of stakeholders to achieve a common objective, although the challenges of this approach are also recognised (Wilmer et al. 2022, Bridle & Price 2009). This paper outlines the co-design approach of the RLS project, the key outcomes of the project and provides recommendations in undertaking collaborative, co-designed research for successful producer engagement, industry collaboration and adoption of research outcomes in rangeland grazing systems.

Co-design approach and review method

The RLS project was co-designed, with project objectives, activities, deliverables, methods and data collection developed in consultation with 12 project partners. This approach was intended to ensure relevance and practicality of project objectives and deliverables and maximise adoption of learnings by producers in Western NSW rangelands. At the centre of the project was the involvement of four 'core' producers who approached the researchers and/or were identified through project partners with a common goal of achieving environmental, business and productivity outcomes across their properties. The producers collaborated with the project team to identify, implement and monitor practices they decided would be beneficial to achieving the goals they set for their property. Methods to monitor and evaluate the success of management interventions and practices were developed to ensure outcomes of interest to producers were measured and reported on. Where possible, the core producers were involved in the establishment of trials, collection of data and photo points following trial installation, and in communication of trial results through field days, newsletters, scientific publications, case studies, project milestone reports and the final project report. Other project partners included Resource Consulting Services, Western Local Land Services, Australian National University, CarbonLink, Select Carbon, Soils for Life and Meat and Livestock Australia. The project engaged producers from an additional 26 livestock production businesses in western NSW to build their capacity and support their decision-making regarding adoption of practice change on up to 1M ha of grazing land in western NSW. These producers were involved through data collection and monitoring across their own properties, training, online discussions with subject matter experts and field days.

Research trials were established to investigate effects of management interventions identified as areas of interest by the producers for their context and goals, with support of the project team. Interventions included water ponding, deep ripping, intensive short-duration animal impact, gypsum, soil biological stimulants, hard-seeded annual legumes and mixed-species cropping. Additional monitoring investigated the effects of planned grazing management on ground cover, soil carbon dynamics and relationships in rangeland grazing systems, soil chemistry constraints in NSW rangelands, ground cover trends across NSW rangeland grazing systems, rangeland grazing business profitability, and greenhouse gas emissions from rangeland livestock enterprises.

Over the life of the project, the project hosted 17 in-person field days and workshops on a variety of topics relevant to the project theme, including soil carbon, soil biology, soil monitoring, ground cover, grazing management and natural capital. Additional online workshops, webinars and recorded videos were hosted through the project on a broad range of topics and further extension to a broader audience was achieved via fact sheets, newsletter and media articles, presentations and social media.

Towards the end of the project, a survey to all project partners was distributed to collect feedback on the key successes, challenges and recommendations going forward of the collaborative, co-design approach and the outcomes of the project. 14 responses from 10 of the project partners were received. The findings were further discussed through three focus meetings with the project partners to refine this feedback into key learnings and recommendations, with all project partners provided the opportunity to provide further review and input via email and shared online documents. During this review and from trial and learnings throughout the life of the project, project partners documented key factors for engaging producers in research, development and extension activities in NSW rangelands.

Outcomes and learnings from RLS for collaborative research

Overwhelmingly, project partners considered the RLS a success and identified value in structured and meaningful producer collaboration throughout the project, from inception to delivery, as well as the broad skillset provided through partner organisations. Benefits of this approach included improving the breadth, robustness and relevance of the scientific research, bringing together diverse experience and perspectives, connecting stakeholders and increasing the project reach, producer engagement and participation. Key outcomes of the RLS project included:

- Enhanced producer awareness and capacity building related to management and monitoring of soil, pastures, biodiversity, landscape function, productivity and profitability in rangeland grazing systems
- Improved collaboration and knowledge exchange between producers, researchers and industry stakeholders in the NSW rangelands
- Scientific evidence demonstrating the efficacy of management practices and enhanced understanding of relationships between carbon and environmental variables in data-poor rangeland areas
- Demonstration of environmental, productivity and profitability outcomes of management practices in NSW rangeland grazing systems

Project partners also identified learnings, considerations and challenges of this expansive project team and producer-centric approach, including: 1) an ambitious project scope designed to be multi-disciplinary but which at times led to a lack of clarity and accountability, and was constrained by time and financial resources; 2) at times, limited producer engagement and participation in project activities due to competing events, long distances, low populations, and workload priorities; 3) external factors such as COVID-19 or floods which challenged momentum of the project; and 4) managing expectations of a large and diverse project team, at times with participants pulling in different directions in regards to the delivery of project activities and communication of project outputs. Key to overcoming these challenges was regular, open and respectful communication, recognising the skills and knowledge that stakeholders bring to the project team and taking a participatory approach to all project activities, including in the planning of events and development of project outputs.

Key 'success' factors in fostering producer engagement

Due to the large areas of land managed by producers, and the low population density in this extensive environment, it is critical that rangelands research, development and extension (R, D & E) actively, intentionally, and successfully engages producers to optimise value and potential adoption. At the conclusion of the RLS Project, the following recommendations were developed by the project team which includes the core producers to outline key strategies to foster meaningful engagement with producers, thereby enhancing the overall impact and value of collaborative projects.

→ **Set realistic and achievable R, D & E objectives** and priorities with both producers and industry
→ **Co-design** R & D projects with producers and industry stakeholders to ensure activities are relevant, practical and of interest to target audience and end users of information
→ Outline a **clear value proposition** for producers, including the project outcomes that will be of value to them and their business, now and in the future
→ **Engage producers in all aspects of project**, encouraging active participation and contribution and practical feedback (including project development, monitoring, hosting events, presenting results, reviewing project outputs)
→ **Incorporate producer knowledge** and feedback into project design, activities and outputs

- → **Value the time, expertise and contribution** of producers in the project team, including payment for time and services, ensuring equal partnership and ownership and clear accountability
- → Establish research and demonstration sites '**on the ground'**
- → **Encourage producer-led initiatives** and peer-peer learning. Where possible, have producers present and talk to the experience and results of projects on their property
- → **Highlight success stories, make the research accessible and showcase** R, D & E findings via multiple avenues including field days, workshops, media articles, case studies, podcasts and webinars, to increase reach and engagement
- → **Work with existing producer-led groups** or establish enduring producer networks that collaborate on multiple initiatives to ensure longevity beyond short-term projects
- → **Time events** to avoid 'busy' periods in the production calendar, avoid conflicts with other events, and plan ahead to 'save the date'
- → **Personal connection** is important – ensure regular one-on-one communication between the project team, industry and producers
- → **Provide opportunities for connection** between producers and with industry experts
- → **Provide summary of research or project results** and project data to producers in a timely manner and meaningful and practical format

Conclusion

The Rangelands Living Skin project demonstrated the potential for and application of co-designed, collaborative research and extension to understand and promote management practices that can achieve ecosystem sustainability, productive landscapes and profitable businesses in a semi-arid rangeland environment. The project highlighted the value of producer involvement in all aspects of project design and delivery, alongside a diverse team of stakeholders, and their role in promoting and communicating project findings to support wider adoption beyond the project participants. Engaging producers is critical in maximising the impact of research. Producer participation in R, D & E can be encouraged by ensuring there is a clear value proposition and the project outcomes are relevant to producer needs, valuing the time, knowledge and services provided by producers in the project team, supporting producer-led initiatives and ensuring local support and research activities.

Developing and delivering collaborative R, D & E is not without challenges; however, projects will be more successful if they have a clear project scope and deliverables that are developed collaboratively with all project partners, with regular open communication, flexibility in the delivery of project activities and ensuring sufficient time and budget to achieve project objectives. As political and industry R, D & E priorities and associated funding avenues change, there is an increasing need for a strong value proposition and co-investment by stakeholders to support continued R, D & E in the rangelands. New work will need to consider and facilitate links to First Nations people and would benefit from incorporation of indigenous knowledge and management. Furthermore, future R, D & E would benefit from connecting rangeland regions (across borders, e.g., NSW, QLD, SA, WA), bringing together investment under unified programs of work and sharing information and learnings across broader networks with similarities in production systems. Rangeland grazing systems are a unique and valuable asset for both livestock production and natural capital in Australia. By fostering strong, collaborative relationships among producers and other stakeholders for R, D & E and striving to meet the key principles and strategies for collaborative R, D & E we can drive meaningful progress towards a collective rangelands vision.

Acknowledgements

This research was funded by Meat and Livestock Australia (project L.ADP.2019), led by NSW Department of Primary Industries and Regional Development. The authors gratefully acknowledge the four core producers, the Whyte, Finlayson, Mosely and Humbert/Conder families, for their time, support and honesty, as well as the eight other partner organisations who helped deliver the RLS project.

Abstract

In the semiarid, shortgrass steppe of North America, the Collaborative Adaptive Rangeland Management (CARM) project engaged an 11-member stakeholder group composed of ranchers, non-governmental conservation organization representatives, and state/federal agency personnel since 2012. The stakeholder and research team collaboratively implemented adaptive, multi-paddock (AMP) rotational grazing management, and compared multiple outcomes to those from traditional management of season-long grazing at the same stocking rate during the growing season (mid-May to October). The transdisciplinary scientific team collected and provided to the stakeholders monitoring data about vegetation, livestock, and wildlife habitat, including cattle foraging behaviour and movement dynamics, diet quality, distribution of grazing animals, remotely sensed standing biomass, grassland bird populations, animal weight gains, financial returns, soil health and carbon, and vegetation production, composition, structure, and diversity. A collaborative learning objective was added for co-production of new knowledge and its application to new areas, and increasing trust, respect, and understanding among participants. Iterative decision-making and learning within and across years have been documented through revised objectives, key triggers for drought planning and flexible stocking, and enhanced dashboards for tracking precipitation, soil moisture, forage conditions, and livestock diet quality. A key lesson learned is the importance of open and transparent communications through sustained engagement of stakeholders, leading to increased trust. Research results highlight that higher stocking density with AMP grazing consistently reduces animal weight gains and consequently financial returns in non-drought years through altering foraging behaviour and reducing diet quality. At the same time, vegetation heterogeneity across paddocks is enhanced with AMP grazing, providing a wider range of grassland bird habitat. Future directions include application of new technologies for precision livestock management (e.g., on-animal sensors, near-real-time remote sensing) for flexibility in within-season stocking density to address improvement of livestock performance and profitability, low- and high-vegetation structure for numerous ecosystem services, and greater drought resilience.

Introduction

Born out of the key recommendation to have ranch-scale management-partnerships to address the production-conservation interfaces in rangeland management (Briske et al. 2011), the Collaborative Adaptive Rangeland Management (CARM) project began in 2012 by engaging with a 11-member stakeholder group comprised of private ranchers (n=4, associated with the local grazing association, Crow Valley Livestock Cooperative, Inc.), non-governmental conservation organizations (n=3, The Nature Conservancy, Environmental Defense Fund, and Bird Conservancy of the Rockies) and public land management personnel (n=4, USDA Natural Resource Conservation Service, USDA Forest Service, Colorado State University Extension, and Colorado State Land Board). This resulted in co-produced objectives on vegetation, profitable ranching (including livestock weight gains), and wildlife habitat that formed the basis for the transdisciplinary science team to develop monitoring methods to collect baseline data in 2013 and apply experimental treatments (2014-2023, Augustine et al. 2024). Social learning objectives were added in 2015 (Wilmer et al. 2022).

The overarching goal was to examine how science can be conducted at ranch-level scales with manager involvement to evaluate the effectiveness of adaptive multi-paddock (AMP) grazing management for both production and conservation goals. In particular, we sought to examine an approach to rangeland management that responds to current and changing rangeland conditions, incorporates active learning, and makes decisions based on quantitative, repeatable measurements collected at multiple spatial and temporal scales.

Methods

At the USDA–Agricultural Research Service's Central Plains Experimental Range in northeastern Colorado, USA, a semiarid, shortgrass steppe rangeland ecosystem, and a site in the Long-Term Agroecosystem Research (LTAR) network, we compared CARM, designed to incorporate AMP principles, to traditional rangeland management which is a season-long (mid-May to early October) grazing approach widely used in the region (TRM, Bement 1969). Each treatment was implemented on 130-ha paddocks paired by soils, topography, and plant communities (n=10 pairs). For the first 5 years of the experiment (2014-2018, CARM 1.0), yearling steers in the CARM treatment were managed as a single herd using AMP grazing with rotational movement of steers among the paddocks with planned year-long rest in 20% of the paddocks (i.e., 2 of the 10). In the second 5 years (2019-2023, CARM 2.0), CARM steers were managed as 2 herds using AMP grazing to reduce negative effects of stocking density on livestock weight gains (Augustine et al. 2020) with the same planned year-long rest in 20% of the paddocks. For the TRM treatment, each of the 10 paddocks were grazed by a separate, small herd such that both treatments were grazed by the same total number of steers each year, thereby controlling for annual stocking rate. The stakeholder group was given full agency in deciding how to collaboratively and adaptively manage the yearling steers in the CARM paddocks. See the following papers for additional methodological details regarding vegetation (Augustine et al. 2020), livestock diet quality (Jorns et al. 2024), livestock weight gains (Augustine et al. 2020, Derner et al. 2021), foraging behaviour (Augustine et al. 2022, 2023), grassland birds (Davis et al. 2020, 2021), tiller defoliation (Porensky et al. 2021) remote sensing (Kearney et al. 2022a,b), social learning (Wilmer et al. 2018, 2022, Fernandez-Gimenez et al. 2019), economics (Windh et al. 2019, 2020, Baldwin et al. 2022), and rangeland modelling (Cheng et al. 2021, 2022).

Results

Vegetation: Biomass production did not differ between grazing treatments (Augustine et al. 2020). Ground data collected in the CARM experiment was used to calibrate a new model that predicts daily standing herbaceous biomass at a 30-m pixel resolution from satellite imagery (Kearney et al. 2022a). We observed that frequencies of grazing on a palatable, cool-season grass (western wheatgrass, *Pascopyrum smithii*) were more sensitive to stocking rate than grazing treatments, as roughly two-thirds of tillers remained ungrazed annually indicating that season-long rest is present in both CARM and TRM. Frequencies of tiller regrazing were low (5−15%) and similar between treatments. Although defoliation patterns were similar between treatments at the whole-ranch scale, CARM enhanced spatial and temporal heterogeneity in defoliation frequencies among individual paddocks, as those grazed earlier in the season or for longer experienced more defoliation (Porensky et al 2021). The Agricultural Policy/Environmental eXtender (APEX) model simulated forage production across years and among soil types (Cheng et al. 2021).

Profitable Ranching: Livestock weight gains were consistently lower (11%–16%) in CARM than TRM, except when forage availability and quality were very low due to drought, or exceptionally high due to a very wet year (Augustine et al. 2022). Reduced weight gains in CARM were attributed to the higher stocking density of steers which altered foraging behaviour (more linear grazing pathways) and spatial grazing distribution (Augustine et al. 2023), and reduced diet quality (Jorns et al. 2024). We quantified the contribution of adaptive grazing management (i.e., the stakeholder group' selection of paddock sequence and grazing rotation indicators) to cattle weight gains using a third herd of steers rotated in a randomly determined sequence (i.e., without adaptive management). This comparison indicated that weight gains of adaptively managed cattle were about 25% greater than gains expected under purely random rotational grazing management (Derner et al. 2021). Satellite time series were used to estimate forage quality (Irisarri et al. 2022), which in combination with estimated standing biomass (Kearney et al. 2022a) can provide reliable estimates of yearling cattle growth rates (Kearney et al. 2022b). Daily weight gain was adequately simulated using the APEX model, with dry matter intake, total digestible nutrients, and temporal distribution of dry matter intake the primary influencers of livestock performance (Cheng et al. 2022). Economic evaluations revealed substantially greater costs for fencing and water infrastructure, and for labour in the multi-paddock CARM compared to TRM (Windh et al. 2019). Economic analyses that included long-term market conditions and fluctuations in cattle prices during the seasonal cycle showed that net returns were highly variable between CARM and TRM (Windh et al. 2020).

Wildlife: Relative to TRM, CARM enhanced heterogeneity in vegetation structure across the landscape, benefiting some grassland bird species (Augustine et al. 2024). Resting paddocks for a full year can generate grassbanks that benefit grassland birds that prefer taller/denser vegetation structure such as Grasshopper Sparrow (Ammodramus savannarum), whereas intentional heavier grazing can benefit grassland bird species preferring shorter/sparser vegetation like the Thick-billed Longspur (Rhynchophanes mccownii) (Davis et al. 2020, 2021). These results helped the stakeholder group understand the spatial specificity of managing for grassland bird species and led to refinement in the wildlife habitat objective by accounting for site fidelity of certain grassland birds and trade-offs between suitable bird habitat and vegetation/plant community objectives.

Social Learning: Evidence of shared learning included the individual stakeholders and researchers acknowledging and examining one another's worldviews (Fernandez-Gimenez et al. 2019). We also observed an increase in sister projects implementing lessons from CARM, including Barta Brothers Ranch at the University of Nebraska, and the US Sheep Station initiating a Sheep Collaboratory project. Following the experiment's first major drought in 2020, the stakeholder group and science team co-revised the grazing management plan to more explicitly address drought using precipitation and soil moisture gauges to monitor the amount of precipitation received to date relative to the long-term mean. Stakeholders and researchers have collaborated to organize numerous field tours, develop a symposium on the CARM project at the 2018 Society for Range Management meeting, and produce a video (USDA-ARS CARM video) and a series of fact sheets about shortgrass bird responses to rangeland management, and the CARM project was used as a case study in a report on Agroecosystem Living Laboratories presented to the G20 Chief Scientists in 2019.

Conclusions/Implications

Stakeholders and researchers successfully implemented a participatory, collaborative adaptive management method to co-develop new knowledge about social, economic, and ecological questions in semiarid shortgrass rangelands. This process was often complex and challenging, but those challenges helped inspire learning and developed strong working relationships. Respect, trust, and shared understanding were essential for the collaborative processes and were enhanced by commitment and time for meaningful discussion, debate, and group reflection. This experiment has quantified relationships among adaptive management decisions, cattle grazing distribution, weather variability, and ecosystem services.

To address improvement of livestock performance and profitability, low- and high-vegetation structure for numerous ecosystem services, and greater drought resilience, CARM 3.0 (2025-2029) will have 6 larger paddocks, with 3 replicate pairs of short- and tall-statured vegetation paddocks (383-728 ha, total of 3388 ha), while the TRM treatment will be maintained as 10 paddocks of 130 ha (1300 ha total), each grazed by a separate herd. Stocking rate will remain the same in both treatments within a year, and adjusted annually as decided collaboratively by the stakeholder group. Each of the 3 pairs of CARM paddocks will be grazed by a group of cattle managed adaptively as either 1 or 2 herds depending on weather conditions. Under non-drought conditions, short-statured vegetation paddocks will be stocked at ~50% above the TRM level and tall-statured paddocks at 50% below the TRM level. This will create both a grass bank and more vegetation structure for wildlife habitat in the tall-statured paddocks, while maintaining low structure wildlife habitat and high livestock production in short-statured paddocks. Movements of steers between the short- and tall-structure pairs of paddocks in CARM will be based on near-real time remote sensing tools (Kearney et al. 2022a) to provide the stakeholder group with maps of vegetation biomass and greenness, combined with demand from recent cattle distribution data via on-animal sensors (GPS and accelerometers).

In addition to the larger scale of paddocks in CARM 3.0, the stakeholder group and science team are currently revising the study objectives, which are incorporating the small mammal black-tailed prairie dogs (*Cynomys ludovicianus*) explicitly into the experiment (they were intentionally not included in CARM 1.0 and 2.0), spatially-explicit zones of management within paddocks for some key wildlife species, a shortened grazing season (ending in early September rather than early October) due to economic benefits (Baldwin et al. 2022), and inclusion of an Amplifier Team for more input regarding public needs and concerns, and strengthening messaging of findings from the project to the public for application, impact, and policy.

12 years of grassland board in Uruguay

Cáceres Bentancor, D[1]; Pereira Machín, M[2]

[1]Ministry of Livestock, Agriculture and Fisheries, Garzón 456, Montevideo, Uruguay. [2]Institute Plan Agropecuario, Br. Artigas 3802, Montevideo, Uruguay

Key words: Grassland, livestock, governance, board

Abstract

Pampas are the only biome in Uruguay, occupying about 60% of the territory and are the main forage resource for cattle and sheep production. Despite this, its value, its resilience to climate change and its provision of ecosystem services are generally underestimated. Almost all of these Pampas, and therefore their conservation, depend on the livestock farmers who own them. In this context, the Grassland Board (GB) was created in 2012, a formal environment within the Ministry of Livestock, Agriculture and Fisheries (MGAP) to improve inter-institutional articulation in pampas, promote the development of technological proposals to increase production in a sustainable way and less vulnerable to climate change, and preserve natural resources. Bringing together 19 public, private, research, extension and farmer institutions and organisations, it is chaired by the Institute Plan Agropecuario (IPA) and operates within the MGAP, which provides the technical-administrative secretariat. The creation of the GB and its experience of institutional articulation in the agricultural sector is an innovative experience that is highly valued by Uruguayan agricultural institutions. Technical proposals such as "Options for the Sustainable Intensification of Livestock Production in Uruguay's Natural Landscapes" have been approved, the "National Day of the Pampas " has been proclaimed by Law No. 20.088, and advice has been provided to decision-makers and to the most important national projects on grassland livestock production. Several high-quality products have been produced, such as publications and awareness-raising events, including the prestigious "The Gold Paspalum" awards. Finally, and after 12 years of intermittent action, the GB has achieved greater articulation between institutions, achieving consensual collective projects and messages. A formal and strong channel of dialogue has been established with the executive and legislative branches.

Introduction

Pampas in Uruguay is the only biome, occupies approximately 60% of the territory and is the main nutritional resource for livestock, most of these are in the hands of private producers and therefore their conservation depends on them. Despite this, their value, their resilience to climate change, and their provision of ecosystem services have generally been underestimated (MGCN, 2019).

In this context, in 2012, the Grassland Board (GB) was created as a formal environment within the Ministry of Livestock, Agriculture and Fisheries (MGAP) to improve interinstitutional articulation in rangelands, promote the development of technological proposals to increase production in a sustainable way that is less vulnerable to climate change and conserve natural resources (MGAP, 2012).

Methods

In this article we will develop how these 12 years of operation have been and their importance for livestock and Uruguayan pampas, we base this work on minutes, publications and interviews with delegates.

Results and Discussion

The GB is composed of 19 public and private institutions and organizations, is presided over by the Institute Plan Agropecuario (IPA) and operates under the auspices of the MGAP, which provides the technical-administrative secretary. The creation of this ambit and its experience of institutional articulation in the agricultural sector represent an innovative experience, highly valued by Uruguayan agricultural institutions (Cáceres and Caballero, 2020). This space brings together government institutions such as: MGAP, the Ministry of the Environment and the National Meat Institute; extension institutions such as: IPA and the Uruguayan Wool Secretariat; Research institutions such as: the National Institute of Agricultural Research, the Faculties of Agronomy and Science of the University of the Republic; producers such as: the National Commission for Rural Development, Federated Agricultural Cooperatives, Rural Association of Uruguay, CREA Groups, Rural Federation, Uruguayan Association of Grasslands Farmers, Uruguayan Society of Rational Grazing, Uruguayan Society of Silvopastoralism and Pampeanas Regenerativas Orientales; regional institutions such as: the Alianza del Pastizal and the Inter American Institute for Cooperation on Agriculture completed their integration.

This integration provides the GB with different points of view and interests, from academia to farmers associations, including the organizations responsible for management and extension. The monthly meeting of representatives of society who directly develop productive activities on pampas with those who generate knowledge and develop technologies, decision makers and articulators, who carry out knowledge transfer, generated an ideal environment for the identification of problems and solutions. The uninterrupted work during 12 years has allowed the consolidation of the area as a recognized and valued space. The good relationship between delegates from different institutions has facilitated the operation and discussion of policies.

Within this framework, the GB has managed to consolidate itself as a space for consultation in livestock farming on the natural environment, advising the Ministries of Agriculture and Environment and other institutions on the main projects on the subject: Family Farmers and Climate Change (2013-2019), Improving the Sustainability of Family Livestock of Family Livestock in Uruguay (2016-2018), Participatory Assessment of Land Degradation and Sustainable Land Management in Grassland and Pastoral Systems (2017-2021); Livestock and Climate project (2019-2023); Grass Management project (2020-2025), to name the main ones. In addition, the GB has shown a great capacity to respond to the different demands posed by the authorities, such as the systematization in less than a month of all the projects related to livestock and campos in Uruguay (MGCN & DGRN, 2020).

In recent years, the GB has set three objectives in its strategic plan:

1. To conserve our country's biome, the Pampas.

2. Improve the economic, environmental and social results of livestock farming on the Pampas.

3. To promote the recognition and valuation by society of the Pampas and its ecosystem services.

With respect to the first objective, the GB managed to put the issue on the agenda, thanks to the exchange with the legislative power it was possible to establish with Law number 20.088 the “National Day of the Uruguayan Pampas” and also has been working on different legislative proposals to improve its conservation (Figure 1), it also provided technical elements for the characterization of grasslands (Stainano and Paruelo, 2017).

Fig. 1. Meeting at the National Parliament between Legislators, authorities and delegates of the GB.

Regarding the second objective, technical proposals such as “A New Paradigm of Intensification for the Campos of Southern South America to Increase Economic and Environmental” (Jaurena, et al. 2021) were agreed upon (Figure 2), and the creation of the Livestock Farming Observatory on Natural Grasslands, which seeks to generate a public good that improves the management of the country's natural resources, facilitating the contribution of information generated and its access and interpretation by actors responsible for their management and administration, ensuring the continuity of the products already generated from the Science and Technique system (MGCN, 2021).

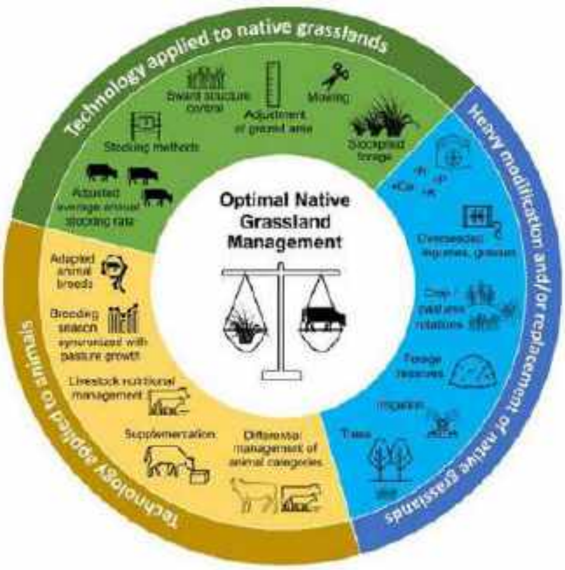

Fig. 2. A new model for livestock sustainable intensification that describes the role of technology applied to livestock management (orange), to modified or replaced native grasslands (blue), and to native grasslands (green) to achieve optimal native grassland management (Jaurena, et al. 2021).

The third objective seeks to promote the recognition of rangelands by the Uruguayan Society, in this sense, several high-quality products have been produced, such as publications, courses for producers and technicians, a traveling photographic exhibition and awareness-raising events such as the recognized “The Gold Paspalum” acknowledgments (Figure 3), which seek to highlight those who have contributed significantly to livestock farming in the Uruguayan Pampas.

Fig. 3. Presentation of "The Gold Paspalum" acknowledgments 2020 (left) and 2024 (right).

Additionally, the GB has achieved a real knowledge and articulation among its member institutions and organizations, materializing this in different extension, research and education projects, executed jointly (MGCN & DGRN, 2020). Furthermore, common messages have been generated, such as "the need for farms to work with higher pasture height", a simple premise that implies an improvement in the productivity and sustainability of Uruguayan cattle ranches.

Conclusions

In its first 12 years, the GB has consolidated and positioned itself as a relevant actor of consultation on rangeland and livestock issues in Uruguay. In addition to making concrete products, the GB goal has always been to "make things happen" regardless of which organization or institution

Acknowledgements

To all the delegates of the organizations and institutions that have been part of this area and whose work has consolidated and strengthened submits it.

[4]Murdoch University

Key words: collaboration; agricultural research; governance; northern Australian agriculture

Abstract
There is broad agreement that research and development is an investment in the future viability and success of an industry. This view has underpinned the establishment of the Western Australian Agricultural Research Collaboration (WAARC). This Western Australian (WA) state government initiative is designed to foster collaboration among WA's participating research organisations (DPIRD, CSIRO, Grower Group Alliance and the universities of Curtin, Murdoch and WA to support WA-centric new projects and research capacity building. WAARC is seeking to support longer-horizon research developing and integrating new areas of science with potential for industry application and to enhance early-career development opportunities for researchers. Its creation is a response to the diminution of a consolidated research capacity in WA. The WAARC initiative currently comprises six program of work, all of which are potentially relevant to the sustainable intensification of agricultural production in northern Australia. Of these, the Northern Agriculture program focuses exclusively on developing research and research capacity in this region. The objective of the program is to increase the Gross Value of Production through intensification of agriculture by 2030 focusing on sustainable growth of irrigated agriculture and the northern beef industry. A key priority in the Northern Agriculture program is the integration of irrigated agriculture and beef production. Growth in agriculture in northern WA focuses on intensifying the cattle industry and optimising irrigated agriculture, ensuring that this is achieved in a way that is environmentally and socially responsible. A related key priority is capturing economic benefit of growth by First Nations' pastoral and related enterprises.

Introduction
In the north of Western Australia (WA), there is strong potential for further development of the agricultural sector, particularly through capitalising on existing resources for irrigated agriculture near Kununurra in the eastern Kimberley region. This region has a geographic advantage for trade with south-east Asia, but its remoteness, climate extremes and low population density have proved challenging for sustaining the workforce required to deliver the research. The WAARC Northern Agriculture program, launched as part of the WAARC initiative by the WA Government, focuses on supporting longer-horizon research projects and fostering collaboration across WAARC's research partner organisations; DPIRD, CSIRO, the Grower Group Alliance and the universities of Curtin, Murdoch and WA. The Northern Agriculture program is developing new opportunities for investment in new projects and capability-building activities to support the agricultural

industry in northern Australia. The program aims to support irrigated agriculture and beef production in northern WA to achieve sustainable growth while ensuring environmental and social responsibility. It is envisaged that this will be achieved through the strategic development of projects with research partners and industry, and by providing leverage to extend other research activities. An emphasis on benefiting First Nation enterprises through economic empowerment and knowledge sharing further underscores the program's inclusive vision. WAARC is developing its governance structure, which has ongoing financial support through funding from each of the partner organisations.

Methods

The review paper draws on insights from secondary data sources, including project reports, official documentation and published literature, as well as contributions from individuals currently involved in the WAARC initiative. It also incorporates case studies of similar initiatives in comparable regions. The review further considers research on agricultural research collaboration and governance models. The aim of the review was to consider the opportunities, challenges and governance issues in agricultural research when implementing a collaborative model for research in northern WA, with a focus on identifying best practices and actionable recommendations.

Results and discussion

Benefits of collaboration

Cross-organisational collaboration is a foundational characteristic of the WAARC initiative, and WAARC encourages a collaborative culture by having a minimum of three partner organisations participating in its funded research activities. A key aim of WAARC is to develop the next generation of researchers, based and focussed in WA, in a way that builds connections with the agricultural industry so that they are better prepared to identify and address emerging challenges. Enabling early-career researchers to develop relationships through projects that link universities with more industry-facing organisations and producers is expected to result in more solution-focused and impactful research (Strycharz et al. 2022). Inter-organisational collaboration is needed to address complex challenges facing agriculture through integrating multidisciplinary expertise, sharing resources, fostering innovation and focusing on industry issues. If coordinated well, research collaboration will enhance the scalability and impact of research outputs, improve funding opportunities and prevent duplication of efforts, thereby increasing efficiency (Jones et al. 2021). Collaborative efforts support knowledge exchange, capacity building and stakeholder engagement, and ensure that research aligns with farmers' needs, industry demands and policy priorities. By fostering collaboration between research institutions and industry, WAARC aims to build capacity and projects with a higher level of collaboration, thereby delivering actionable solutions to agricultural challenges facing WA.

Collaborative research in northern WA

Applying a collaborative research model in northern WA to build research capacity and invest in novel areas of research (e.g. precision agriculture, water-efficient irrigation and sustainable livestock systems) provides significant opportunities to increase sustainable agricultural production. However, human capital and expertise are a significant limitation in northern WA, as it is for most of rural Australia. Conducting research activities in this region also presents additional unique and significant challenges, including harsh climatic conditions, which can be favourable to pests and disease, water scarcity during the dry season, and limitations in soil fertility and pasture quality. The working conditions in this region also present unique health and safety considerations that further complicate experimental work and data collection. Additionally, balancing profitability with sustainability, especially for First Nation enterprises, requires nuanced approaches to ensure economic and social viability. Under these conditions, investing in research tends to entail higher operational costs, longer development timelines and less certain outcomes.

There have been several previous, but ultimately fruitless, efforts to develop collaborative research initiatives to meet the needs of the northern WA agricultural sector. These efforts were initiated in various iterations across the organisations represented in WAARC but lacked the resources to break away from business-as-usual research structures to generate broad collaboration and longevity. However, these proposals contributed to the foundations and momentum for the current WAARC and its Northern Agriculture program. At a national level, supporting agriculture in the north of Australia across WA, Northern Territory (NT) and Queensland has been a central mission of the Cooperative Research Centres for Northern Agriculture (CRCNA). Running from 2017–2027, the CRCNA has been responsible for the establishment of a broad range of research projects across Australia's north, including WA regions, in particular, the Pilbara and Western and Eastern Kimberley.

Having agricultural researchers regionally located in the north of WA (and Australia generally) is important to expedite research activities into industry adoption. Locally based researchers experience greater immersion in local contexts, allowing for deeper engagement with communities, stakeholders and ecosystems. This proximity can foster trust with local groups, including First Nations, and enable more responsive, adaptive research methodologies tailored to the region's unique challenges, allowing quicker uptake by local industry as barriers to adoption are identified through co-design and local networks/relationships. A fly-in fly-out (FIFO) model can reduce long-term costs and allow researchers access to peers, mentors, expertise as well as specialised research facilities and broader resources based in urban centres.

The FIFO model has been widely adopted in other industries of the WA economy in the north and other regions to ensure the supply of highly specialised and credentialled experts through to low-skilled workforce (McKenzie & Hoath 2017). The resources sector has the economic capacity to fund both well-organised FIFO logistical process as well as offer attractive financial compensation for the more unorthodox work roster. Public institutional employment models and conditions, however, are often neither flexible enough nor resourced sufficiently to enable the FIFO model to operate from the major city centres. The challenges are similar for rural-based staff to work for parts of the year in the region during the field season and another region/office in the off-season, despite primary producers and other parts of the industry moving to this model. For example, many of the current generation of broadacre farmers are now opting for a Drive-in Drive-out (DIDO) lifestyle with many working between large city centres on the coast and their inland rural properties, while those in the north of WA do the same over the wet season. Nevertheless, these FIFO/DIDO approaches risk limited continuity and weaker relationships with local stakeholders, are higher in cost, and may contribute to a less nuanced understanding of regional dynamics, which could undermine the effectiveness and relevance of research outcomes. Balancing these models requires careful consideration of the project's objectives, regional needs and resource allocation, with no clear preferred model due to the substantive pros and cons for each (McKenzie & Hoath 2017).

WAARC is expecting to play a key role in supporting targeted research activities and recruiting and providing ongoing support to early-career researchers over and above traditional pathways and funding. Providing additional funding for industry-facing PhDs and supporting appointment and retention of early-career research positions will help to alleviate some staffing shortages in northern WA and foster industry engagement with postgraduate researchers through its PhD research scholarship program, a key objective of WAARC. This program helps to engage early-career researchers who wish to align their research with the Northern Agriculture program goals and potentially build relationships with local industry and remote regions that may not have been available otherwise. WAARC also provides the network of WA-based mid- and late-career researchers, and national connections via CSIRO, who can provide mentoring and support for these WAARC early-career researchers irrespective of the lead partner organisation. The WAARC model (including an 'Agricultural Technologies' program) is seeking to expedite new technologies, such as augmented reality, providing novel solutions for remote research capacity.

Developing governance models

Effective governance underpins successful collaboration. The WAARC management team includes representation from participating organisations and processes such as workshops to ensure broad participation among collaborating partners. In the Northern Agriculture program, the small scale of agricultural research in northern Australia, particularly in the cattle industry, means that the pool of potential research participants is quite small. The WAARC governance structure assists across a range of areas including agreeing on priorities, communication, contracting and an equitable distribution of resources. Australia's Cooperative Research

Centres (CRCs) have a long history of enabling research, and their experiences are valuable in designing and improving WAARC's governance framework.

WAARC currently operates via a memorandum of understanding and a Steering Committee, which meets regularly to review proposed research activities and to provide strategic guidance. These committees are a common feature of joint venture-style structures in WA. The longer-term organisational structure of WAARC is being reviewed and will likely change to a more suitable model for the organisation in the long term. The investment governance structure for WAARC should incorporate a robust framework with clear investment policies, risk management protocols, and accountability mechanisms to safeguard the fund's sustainability and optimise returns for innovative projects and capacity-building initiatives. It must also align with WAARC's funding priorities to support high-level innovative projects and strategic research areas, maximising the impact of the fund's investments. To be successful, WAARC must seamlessly integrate capacity-building initiatives to enhance research capabilities and develop human capital within its organisation and partner entities, as previously outlined. The current structure is designed to support agile decision-making, particularly in fund allocation, while embedding long-term sustainability measures such as financial stewardship, performance evaluations, and strategies to replenish the investment fund. Flexibility is a critical aspect of this framework, allowing WAARC to pivot as needed to address emerging agricultural priorities. For example, recent investments by WAARC in polyphagous species (e.g. shot-hole borer beetle) research have aimed to mitigate damage caused by this insect pest to urban and agricultural trees.

WAARC also plays a pivotal role in future preparedness, ensuring research capabilities are ready to support rapid responses to escalating challenges in northern WA, such as biosecurity threats, environmental concerns or trade market disruptions. However, administrative coordination across the initiative presents unavoidable complexities, which has occasionally slowed contracting and project initiation. Specialist staff have been instrumental in managing these constraints, and further administrative improvements are anticipated as the WAARC initiative continues to mature.

Conclusion

The WAARC Northern Agriculture program exemplifies a strategic approach to addressing regional agricultural challenges through research collaboration. While opportunities abound, addressing the unique challenges of northern WA requires robust partnerships, governance and flexibility. Institutional flexibility to enable work-life balance and the ability to work part-time in the north during favourable parts of the year and in other regions for other parts and/or via a FIFO model need to be considered. The program's focus on integrating irrigated agriculture with beef production demonstrates the potential for scalable and sustainable agricultural models. However, leveraging these opportunities will depend on overcoming logistical barriers, including developing a locally based skilled workforce, and ensuring that First Nations' communities are integral co-beneficiaries.

Valuing traditional and Indigenous knowledge: evolution, threats and opportunities

Mongolian herders' plant knowledge: intergenerational transfer and change

Jamsranjav, C[1]; Fernández-Giménez, ME[2]

[1]World Wide Fund for Nature Mongolia Program, Ulaanbaatar, Mongolia
[2]Department of Forest and Rangeland Stewardship, Colorado State University, Fort Collins, CO 80523-1472, USA

Key words: Traditional Ecological Knowledge; rangeland, plant, Mongolia

Abstract
Traditional Ecological Knowledge (TEK) is increasingly recognized as an important component of biocultural diversity and a potentially valuable resource for adaptation to future changes. TEK is a vibrant knowledge system held by geographically and socially defined communities in relation to their day-to-day interactions and relationships with their environment and is transmitted between generations. With the socioeconomic changes in the last 30 years in Mongolia, many young herders have moved to cities for jobs and education and many elder herders have followed them, to help care for grandchildren and to avoid the increasing harshness of livestock herding caused by climate change and rangeland degradation. With these demographic and social changes, some fear that TEK is being lost. Therefore, we sought to document herders' current plant knowledge, and to compare the knowledge of younger and older herders, and those living in remote rural and settled areas. We asked 30 herders in four subdistricts in Arkhangai province, Mongolia to list all the plants they know that grow in their community and to discuss their uses. Knowledge of plants and their uses did not vary between rural and settled areas, likely because many older participants had moved to the province center, taking a lifetime of herding knowledge with them. Plant knowledge did vary with age. Younger herders didn't mention certain species that have declined in the local environment, likely due to environmental changes. To support conservation and intergenerational transfer of plant TEK, we are working with rural herders, schoolteachers and the district cultural center to develop school curricula and museum exhibits featuring local plant TEK.

Introduction
Traditional ecological knowledge (TEK) is increasingly recognized as an important component of biocultural diversity and a potentially valuable resource for adaptation to future changes. TEK is a vibrant knowledge system held by local place-based communities in relation to their day-to-day observations, interactions and relationships with their environment (Berkes 1999, Fernandez-Gimenez and Fillat 2012). TEK is accumulated, practiced and transferred from generation-to-generation and it holds place-based values and belief systems (Berkes et al. 2000). The connection between cultural and biological diversity as known as biocultural diversity emphasizes the coupling of environment/nature and culture (Loh and Harmon 2005; Seele et al. 2019). Plant biodiversity indicates the richness of the rangeland resources and their health, on which herders' dependent on plant resources for livestock forage, food, medicines, firewood, construction of dwellings as well as ritual and cultural practices. Cultural diversity is manifested from individual ideas to entire community and culture (Loh and Harmon 2005).

Many TEK studies warn about potential loss of these knowledge systems due to social-ecological and political changes (Fernandez-Gimenez et al,. 2017) and some recent studies also emphasize the importance of TEK application for adaptation to future changes considering of dynamic nature of the TEK (Peter et al. 2024). Therefore, providing means for younger generations to access TEK is critical contribution to preserve, practice and use TEK for adaptive management in a changing world. Mongolia is one of the few countries practicing mobile herding on its vast open native rangelands (Fernandez-Gimenez 2000, Honey church 2010). However, overgrazing and climate change are degrading Mongolia's rangelands (Liu et al. 2013, Zhao et al. 2015), and at same time herding culture is fading due to socio-economic changes (Fernandez-Gimenez et al,. 2017). In Mongolia, TEK is transmitted between generations, elders sharing knowledge with children and grandchildren within families during day-to-day activities, and with young herders of communities when they meet and exchange information on the pasture (Peter et al. 2024). Current, ecological and socio-economic changes are thought to weaken and alter access to, transfer and, practice of TEK in Mongolia in two main ways. First, many young herders have moved to cities for jobs and education and many elder herders have followed them, to help care for grandchildren and to avoid the increasing harshness of livestock herding caused by climate change and rangeland degradation. Second, introduced techniques (herding via car and motorbike) and technologies (mobile phone, satellite collar) reduce workloads and save time for herders, but also limit the practice of TEK and weaken herders' close interactions with and observations of their environment (Seele et al. 2019). In light of these changes, we sought to document herders' current plant knowledge, and to compare plant knowledge across herders of different genders, ages and living in remote rural areas versus settlements. We expected women and men both to know many plants, but we expected that the types of plants they emphasized might differ. For example, we thought that women might mention more plants used for food and human medicine and that men might mention more forage plants. We expected older herders to hold more knowledge about specific plants and their uses. We expected herders in more remote rural areas to maintain more traditional practices and therefore to hold more knowledge of plants, in terms of number of plants and their uses.

Methods

We conducted our study in four different subdistricts (baghs) of two districts (soums), Ikh Tamir and Undur Ulaan, of the Arkhangai province. Arkhangai lies 500 km to the northwest of Ulaanbaatar, the capital city of Mongolia. These four baghs include Azarga bagh of the Undur Ulaan soum which is distant from the soum and aimag centers, Bayangol bagh of the Undur Ulaan soum which is very close to the soum center, Khan Undur bagh of the Ikh Tamir soum is close to the soum and aimag centers, and lastly, Tsetserleg VII bagh which is very close to the aimag center. Arkhangai aimag is in the mountain and forest region, where forests, rivers and lush vegetation support four types of livestock, horse, cattle, yak, sheep, and goat.

We interviewed herders during the spring, early summer, and fall of 2022. We recruited interview participants using a snowball method and sought to include herders of all ages and herding experiences across these four baghs. All interviews were conducted in Mongolian and participants were asked to list all the plants they know and that grow in their homeland (*nutag*). After a participant named all the plants they knew, we asked about each plant's use either as medicine, food, and/or livestock forage. Finally, we asked them to share their observations about increasing or decreasing trends in abundance of each plant. Data collection was conducted with participants' free, prior and informed consent and conducted under the Purdue University Institutional Review Board (IRB) protocol (# 2021-1083). All interviewees read and signed the consent form before we started our interview. In total, we interviewed 30 herders, of which 24 were men, and 6 were women. Seven of the interviewees are from Azarga bagh, six are from Bayangol, eight are from Khan Undur bagh and nine are from Tsetserleg. Seven of the 30 interviewees are people aged above 61 years old, 15 are aged between 41 and 60 years old and 8 are people under 40 years old. The average age of the participants was 50, and the oldest and youngest participants were 81 and 25 years old. Interviews were audio recorded and transcribed for analysis. We entered free lists of plants in the local and scientific names into Excel, calculated descriptive statistics and a cognitive salience index (Sutrop 2001) from free list data. Only plants appearing on two or more lists are included in this calculation. We used one-way ANOVA to test if lists generated by four baghs and three age groups differ from each other and t-test to assess gender differences.

Results

By gender: Men listed more plants than women (t=2.236, df=26.16, p=0.034). Women generated 56 plants' list. Ten of the listed by women are good livestock forage plants, 15 are medicinal plants, 18 are for human food use such as for making tea, jam and juice, other uses such as firewood, hair washing, carpentry. Of the women listed plants, 11 plants are decreasing, and two plants are increasing. Plants with greater CSI listed by women are *Pulsatila ambigua* (*khukh yargui*), *Urtica* species, and *Artemisia frigida* (*agi*), *Pulsatila flavescens* (*shar yargui*), *Gentiana azura* (*khukh degd*) and *Thymus gobicus* (*ganga*).

Men listed a total of 125 plants, including 47 livestock forage species, 42 medicinal plants, and 32 plants used for human food and other purposes, such as firewood and carpentry. Of the total listed, 33 plants are decreasing, and 10 are increasing. Plants with higher CSI listed by men include livestock forage species such as *Elumus chinensis* (khiag), *Stipa species* (nariin uvs), *Pulsatila ambigua* (khukh yargui), *Artemisia frigida* (agi), *Gentiana azura* (khukh degd), and *Allium scheonoprasum* (khumkheel), all of which are decreasing.

By age: There was no significant difference in the average number of plants listed by three different age groups (p=0.13). However, younger herders listed fewer plants, while older herders listed more.

Young herders (below 40) identified 24 forage, 20 medicinal, and 12 human-use plants out of a total of 69 plants listed. They observed the growth trends of 11 plants, with seven decreasing (2-livestock forage, 2-medicinal, 3-human use), three increasing, and one plant showing differing growth trends according to two herders. Plants with greater CSI are *Stipa species* (nariin uvs), *Elumus chinensis* (*khiag*), *Pulsatila ambigua* (*khukh yargui*), *Gentiana azura* (*khukh degd*), *Artemisia macrocephala* (*Tsarvan*) and *Gentiana algida* (*Vanjingarav*), *Allium scheonoprasum* (*khumkheel*), *Artemisia frigida* (*agi*).

Middle-aged herders (41-60 years) listed 46 forage, 27 medicinal, and 28 human-use plants out of a total of 94 plants. They observed the growth trends of 34 plants, all of which 26 plants (15-livestock forage, 9-medicinal, 2-human use) are decreasing, six are (3-are livestock use, 2-medicinal, 1-human use) increasing and two plants showing differing growth trends according to four herders. Plants with greater CSI listed by this age group are *Pulsatila ambigua* (*khukh yargui*), *Pulsatila flavescens* (*shar yargui*), *Gentiana azura* (*khukh degd*), *Allium scheonoprasum* (*khumkheel)*, *Sanguisorba officinalis* (*Sud uvs*), *Oxytropis myriophilla* (*tagsh*), *Elumus chinensis* (*khiag*) and *stipa* species (*nariin uvs*).

Older herders (61+ years) listed a total of 97 plants, including 21 forage species, 31 medicinal plants, and 15 human-use plants. They observed the growth trends of 24 plants, with 21 decreasing and 3 increasing. Plants with higher CSI listed by this age group include *Artemisia frigida* (agi), *Festuca lenensis* (Botuuli), *Elumus chinensis* (khiag), *Allium scheonoprasum* (khumkheel), *Stipa species* (nariin uvs), *Urtica species* (Khalgai), *Gentiana azura* (khukh *degd*), and *Rheum species* (*Gishuune/Tsoorgono*).

By location/lifeway. There was no significant difference (p value=0.39) in the number of plant listing among herders in the four baghs. Herders in Tsetserleg (aimag center) listed more plants (99 plants) than those in the other three baghs followed by Khan Undur (81 plants) and Azarga (75 plants) baghs. Herders in Bayangol bagh listed fewer plants (62 plants) than those in the other three baghs. Common livestock forage plants listed by herders in all four locations include *Stipa* species, *Elumus chinensis* (khiag), *Gentiana azura* (khukh degd), *Pulsatila ambigua*, and *Artemisia frigida* (agi). Plants with greater CSI listed by herders of the four baghs are shown in the table 2.

Herders in the Tsetserleg emphasized that 9 of the totals listed of 97 plants are livestock forage plants, 33 are medicinal, 12 are for human use. Participants in this bagh observed the growth trend of the only 25 plants and 16 (4 plants-livestock forage, 6 plants-medicinal, 10 plants-human used) of these plants are decreasing and 9 are increasing. Herders in Khan Undur listed as 39 livestock forage plants, 25 medicinal, 22 plants for human use out of 81 plants. They also observed the growth trend of the 19 plants, of which 13 (5 plants-livestock forage, 7 plants-medicinal, 1plant-human use) are decreasing, 6 are increasing. Herders in Azarga bagh listed

27 plants as livestock forage, 19 medicinal, 16 plants for human use out of 75 plants. They also observed the growth trend of the 17 plants (8 plants-livestock forage, 5-medicinal, 2-human used), of which 15 are decreasing, 2 are increasing. Herders in Bayangol bagh listed 18 plants as livestock forage, 8 medicinal, 10 plants for human use out of 62 plants. They also observed the growth trend of the 10 plants, of which 9 (5 plants-livestock forage, 3plants-medicinal, 1 plant-humanuse) are decreasing, one is increasing.

Discussion [Conclusions/Implications

Overall, plant knowledge did not vary by age or location but differed by gender. Women have more knowledge of plants used for human purposes, reporting that 32% of the listed plants are for food or other uses, 27% for medicine, and 18% for livestock forage. In contrast, men reported that 38% are livestock forage, 34% are medicinal, and 26% are for human use. Men noted a decline in forage plants like *Festuca lenensis* (Botuuli) and *Allium scheonoprasum* (khumkheel), while women observed plants used for human purposes, such as *Thymus gobicus* (ganga), used for washing hair and burning as incense. Both men and women noted an increase in *Artemisia dracunculus*, along with other weedy species such as *Artemisia macrocephala*, *Chenopodium album*, *Urtica species*, and drought-tolerant *Stipa krylovii* (shivee) which observed by men. Our findings suggest that women are more likely to mention food and medicinal plants, while men focus more on forage plants. Men typically manage livestock grazing, while women handle domestic chores like child and elder care, food preparation, and dairy processing, reflected in their responses. Due to an unbalanced sample (men = 24, women = 6), our conclusions are preliminary.

There was no significant difference in the number of plants listed by the three age groups ($p = 0.13$). However, younger herders listed fewer plants than older groups. Younger herders did not mention plants like *Festuca* (botuuli), *Oxytropis myriophilla* (tagsh), and *Rheum species* (gishuune/tsoorgono), which older herders listed. These plants, important for livestock forage, are declining due to climate change and overgrazing (Khishigbayar et al., 2014; Gantuya et al. 2021). Young herders, traveling by car or motorbike, have less opportunity to gather plant knowledge and observe the environment. They noted growth trends for only 16% of the listed plants, while middle-aged herders (41-60 years) observed 36%, especially more forage plants. Older herders listed more plants but observed fewer growth trends, likely due to moving to soum and aimag centers, limiting their ability to track environmental changes.

Common livestock forage plants listed by herders in all four locations include *Stipa* species, *Elumus chinensis* (khiag), *Gentiana azura* (khukh degd), *Pulsatila ambigua*, and *Artemisia frigida* (agi). We expected herders in remote areas to have more detailed plant knowledge. While Tsetserleg (urban) herders listed more plants overall, they mentioned fewer forage plants and more medicinal plants than other baghs. Herders in Tsetserleg observed a greater decline in plants used for human purposes (e.g., pine nuts, willows, wild berries) compared to forage and medicinal plants. Many older participants had moved to the aimag center (Tsetserleg), taking their herding knowledge with them. Contrary to expectations, living in the aimag center didn't equate to a lack of experience, but this knowledge isn't being applied or passed on to younger generations (Peter et al,. 2024). In contrast, herders in Azarga and Khan Undur listed more forage plants, with herders in Azarga and Bayangol observing a decline in forage plants, where livestock population increased 3 times over the last twenty years. while those in Khan Undur noted a decline in medicinal plants.

Key words: herd breeding; herd sharing; mobile grazing; resilience; traditional ecological knowledge

Abstract

In the face of significant socio-economic and environmental challenges, traditional ecological knowledge (TEK) systems globally have shown remarkable resilience. This study investigates the resilience of traditional ecological knowledge by analysing three pastoral practices—mobile grazing, herd breeding and herd sharing—in East Ujimchin Banner, Inner Mongolia, China. Using interviews, participatory mapping and surveys, we delve into the dynamic nature of these practices, noting both changes and continuities. Our findings reveal that, while some elements of these three practices have changed, many others have persisted and remain active. For instance, in the context of mobile grazing, despite the changes in moving distance and frequency, herders still practise strategic seasonal movements within the limited pastures they have available. Another important finding is that each of the practices analysed serves diverse functions, such as restoring herd productivity, maintaining ecological balance and adapting to changing climate. Furthermore, the practices under study also have overlapping functions, aiding each other in aspects like climate adaptation. For instance, mobile grazing facilitates access to better pastures in harsh weather conditions, while herd sharing offers a collective approach to managing risks.

Introduction

A large body of research demonstrates the critical role traditional knowledge systems play in maintaining the resilience and sustainability of socio-ecological systems. These systems impact on environmental conservation, agriculture, health and community governance (Berkes et al. 2000, Molnár et al. 2023). Despite these advances, a hierarchical separation persists between scientific and traditional ways of knowing, rooted in colonial legacies and compounded by educational systems, policies, market economies, urbanisation and globalisation. These factors, alongside environmental and socio-ecological changes, challenge local traditional communities' ability to perceive, function and sustain themselves as their ancestors did. This challenge is reflected in extensive literature that often reports the loss or erosion of traditional knowledge systems (Fernández-Llamazares et al. 2023). Reporting on this loss can highlight vulnerabilities and mobilise global support to protect these cultural legacies. However, viewing these knowledge systems solely as fading risks their 'museumification', reducing them to static knowledge from the past rather than recognising them as dynamic and adapting entities (Berkes et al. 2000, Reyes-García et al. 2014).

This study examines the resilience of the TEK system among pastoral herders in East Ujimchin Banner, Inner Mongolia, China, focusing on the intrinsic resilience mechanisms within TEK. We analyse three traditional herding practices—mobile grazing, herd breeding and herd sharing—to see how these practices have historically enabled herders to adapt to past environmental changes and how they may continue to support adaptation to contemporary socio-environmental challenges.

Methods

This study is based on nine months of fieldwork in East Ujimchin Banner, Inner Mongolia, China. Three villages were selected as study sites. We combined both qualitative (semi-structured interviews and participatory mapping workshops) and quantitative methods (survey) for data collection. To gain a comprehensive understanding of traditional practices in the area, the study began with interviewing three key participants. Through these interviews, we identified mobile grazing, herd breeding and herd sharing as the practices that contributed the most to adapting to climate variability. To delve deeper into the details of these practices, semi-structured interviews were conducted with other elders (n=40). We also conducted three participatory mapping workshops in each village with 12 local elders to document historical mobile grazing practices. To collect data on current application of the three practices, we used data from semi-structured interviews to design both individual and household survey. Additionally, we organised household participatory mapping workshops with 30 randomly selected households to understand current mobile grazing practices. For data analysis, a mix of qualitative and quantitative methods was used.

Results

Mobile grazing practice

Regarding the motivations, according to interview responses, mobile grazing was core to maintaining livestock health and productivity, ecological balance and climate adaptation. Comments made during household mapping of current movements show that nowadays herders continue practising mobile grazing primarily to rest and regenerate pastures (93%). Seven participants cited the improvement in livestock health through varied pastures as their motivation, while two participants noted the importance of maintaining tradition.

Traditionally, mobile grazing in the area was characterised by frequent movement, careful selection of seasonal pasture locations, strategic timing of movements and long-distance mobility during extreme weather events. Regarding when to move, participants mentioned that changes in temperature, pasture quality or productivity of grazing areas determined the timing of seasonal movements. Participants also reported that, in the past, East Ujimchin herders also employed long-distance mobility to cope with severe winter events that severely restricted access to pastures.

Since 1984, mobile grazing has experienced significant changes, characterised by reduced movement frequency, fewer seasonal pastures and diminished long-distance grazing. Despite these changes, a key element of mobile grazing has persisted: seasonal utilisation of pastures. Data from 30 participatory household mapping sessions show that households with over 1333 ha of land typically have three seasonal pastures. The households managing pasture areas ranging between 667 and 1333 ha have two seasonal pastures. Among participants with less than 667 ha, micro-mobility is the predominant strategy. As in the past, the type and number of seasonal pastures continue to be influenced by the available pasture area and landscape characteristics.

Herd breeding practice

In terms of the motivations, participants reported traditional breeding traits for selecting male livestock helped ensure that the livestock are productive, well suited to the local climate and reflective of cultural values. According to the survey data, a large majority of participants, 94% (n=213), believe that, in general, breeding practice now significantly contributes to restoring herd productivity. Moreover, 78% (n=178) of participants view breeding as crucial for enhancing their livestock's resistance to winter disasters. Similarly, most participants agree on the ability of breeding to enhance livestock resistance to drought (76%, n=173). When considering the importance of breeding to increase resilience to pasture shortage, levels of agreement were more varied, but still most informants agreed (62%, n=141).

Through interviews, we identified 19 traits across the five types of livestock, each serving different functions, including enhancing productivity, improving climate resistance and preserving cultural values. Regarding the functions of identified breeding traits, high productivity is particularly emphasised, with six key traits across different livestock types specifically valued to maintain productivity. Climate resistance traits are also considered crucial to ensure that livestock can withstand harsh weather conditions. Beyond their practical functions, the participants noted the physical traits of livestock also embody unique cultural identities and beliefs.

Parallel to changes observed in mobile grazing, breeding practices in East Ujimchin have also undergone significant transformations since 1984. Certain selection traits, such as 'single-colour selection' of stallions and bulls and 'born in the middle of lambing season' of rams have a noticeable shift in awareness and use. Moreover, bucks and bulls are now preferred without horns. Despite these changes, 30 traditional traits continue to be sought, although their use varies. For selecting a ram, most participants follow four traditional breeding traits: selecting animals with big and even tails (84% of survey participants), long and straight backs (84%), wide hips (84%) and the (82%). Stallion selection continues to value traits such as lineage (86%), square hip (71%) and long back (70%). In the case of bulls, traits such as lineage (72%), thick body skin (69%) and balanced and even horns (48%) remain important.

Herd sharing practice

As participants reported, traditionally, this practice contributed to fostering societal equality. During the collective era, it was also practised to maintain herd-pasture balance, address labour shortages, minimise climatic risks, sustain herd growth, and help herders with few or no animals to increase their herd size. Household survey results show that the primary reason for engaging in herd sharing now is to mitigate land shortages, cited by 38% of households. Other significant reasons include helping families in need and addressing labour shortages (18% each). Additionally, 15% of households use herd sharing to increase their herd numbers, and 7% of participants use it as a strategy to adapt to severe climatic events. A smaller portion, 3%, view herd sharing as an important tradition that should be preserved.

In the past, families with larger herds would share some of their livestock with families with fewer or no livestock. In return, the sharing families paid the labour of caring for the livestock by offering some of their livestock, along with meat and dairy products, to the host families. Later during the 1950s, when a family wanted to share part of its herd, there was a requirement that 60–70% of the herd be female, with 30–40% of the newborn offspring belonging to the host family after one year.

Survey data show that most households (81%) know about the herd-sharing practice, and 25% of the households either have shared their livestock with other families or received livestock from others. Compared to past practice, now it is more common to receive/pay money rather than take/give back offspring. Overall, based on survey data, herd sharing is perceived positively for its ability to address several critical challenges faced by herders. A significant portion of households (82%) believes that herd sharing can help herders manage land shortages; 73% of households also recognise its role in dealing with current labour shortages. Additionally, 70% of households perceive herd sharing as an effective strategy to combat land degradation, and more than half of them (52%) reported it helpful in mitigating severe climatic events.

Discussion

One of the main findings from our work is that, while various elements of all three practices have changed, many others have persisted and remain active. In the context of mobile grazing in East Ujimchin, despite the changes in moving distance and frequency, herders still practise strategic seasonal movements within the limited pastures they have available. They do so by careful observation of the subtle signs in the pastures, the landscape and changes in vegetation. For families with insufficient pasture area to support distinct seasonal grazing, micro-mobility is adopted. Aligning with these findings, despite the sedentary or semi-sedentary reality of many pastoralists globally, it is crucial to remember that mobility remains an integral component of herding life (Varga et al. 2020, Na et al. 2018).

Another important finding from our study is that each of the practices analysed serves various functions. Historically, these practices have been multifunctional, addressing the past needs. Currently, as environmental and socio-economic conditions evolve, new functions are also emerging, allowing these practices to adapt and respond effectively to contemporary challenges. If we imagine East Ujimchin pastoral knowledge as an ecosystem, then different types of knowledge can be understood as organisms within this ecosystem. Just as species populations in an ecosystem perform diverse roles—from nutrient cycling to climate regulation—also different types of traditional knowledge perform multiple functions. Research suggests that ecosystems with greater functional diversity are more resilient to disturbances and changes, as this diversity enables multiple adaptive responses to environmental fluctuations, thereby maintaining ecosystem stability and facilitating recovery after disturbances (Días & Cabido 2001). Similarly, we argue that the diverse functions of TEK may contribute to the resilience of the knowledge system itself, ensuring it remains dynamic and capable of withstanding socio-environmental shifts.

Another finding is that the studied practices play common functions together. TEK systems are inherently holistic and complex; within them, diverse knowledge and practices work synergistically to adapt to and manage the natural environment effectively (Iaccarino 2003). For example, in adapting to climate variability, herders do not simply rely on weather forecasts, but also emphasise strategic herd breeding to select traits that improve livestock's drought tolerance and productivity. In East Ujimchin, the three practices also complement each other in terms of climate adaptation. Mobile grazing is crucial during severe weather events, allowing herders to move their livestock to more suitable pastures. Breeding is vital for climate adaptation, focusing on traits that improve weather resilience. Herd sharing offers a community-based approach to managing climate risks. This functional complementarity of knowledge allows pastoral communities to approach challenges from various angles. But more importantly, we argue that the interplay and synergy among functions may contribute to the resilience of the knowledge systems through maintaining the essential ecological, economic and socio-cultural functions of these systems.

Acknowledgements

The authors extend their sincere gratitude to the community members of East Ujimchin Banner for their invaluable participation and knowledge contributions to this research. Use of ethnoveterinary practices among transhumant/pastoral farmers in hilly areas of Jammu and Kashmir, India

Azad, MS[1]; Choudhary, SI[2]; Kour, K[1]; Upadhyay, L[1]

[1]SKUAST-Jammu
[2]Secretary Tribal Affairs Jammu and Kashmir

Key words: transhumance; *Trachyspermum ammi; Curcuma longa*; herbal medicine**;** Gujjars

Introduction

Transhumance is a unique phenomenon of seasonal migration of families along with livestock, mostly to higher altitude in summers and returning to the lower plains in the winter. The vertical migration follows the climatic pattern suitable for growth of livestock and is driven by the availability of sufficient grasslands or rangelands (Photograph 1). Jammu and Kashmir has a large transhumant population (0.6 million people) which is more than the total population of countries like Maldives, Iceland, Luxemburg, Brunei and many more. The livestock economy is the backbone of transhumant families, in fact the only mode of sustenance. The entire socio-cultural-economic model of transhumance revolves around the core of livestock rearing, mainly goat/sheep husbandry and dairying. Traditional and household ethnoveterinary treatment is prevalent in these hilly areas and forms the first line of defence for treatment of livestock (Ishtiyak & Hussain 2017, Tali et al. 2019, Mir et al. 2022). Herbal and plant-based ethnoveterinary medications form the major part of livestock treatment in these areas (Sharma et al. 1989). These traditional herbal remedies are cost effective, easily available and less technical, which makes them more popular than Western medications. The reliance on ethnoveterinary medication among the tribal population of Reasi and Udhampur Districts inspired the current study with following main goals:

1) To identify and document the different traditional plant-based treatments used by tribal people
2) To document the type of diseases being treated with these plants and their byproducts
3) To investigate the level of trust by tribal people in these traditional remedies.

Photograph 1: Transhumant migration in search of grassland

Methods

The main study areas were the remote villages of Reasi and Udhampur Districts of Jammu and Kashmir with a high density of tribal/transhumant population, mainly Gujjar and Bakarwal. Reasi and Udhampur are predominantly hilly districts with variable climatic conditions, ranging from subtropical to semi-temperate. These districts mainly can be divided into 'hilly' and 'low-lying hilly' areas. They have dense forest areas that host a diverse group of medicinal and herbal plants used for many health treatments in both humans and animals. Crops and livestock are the major sources of livelihood for these communities, who often move with their livestock to different parts for grazing. The data were collected by means of questionnaires from respondents in eight villages in each of the two districts surveyed. Interviews and discussions were the main methods for collecting information based on the questions in the questionnaire. Information was collected from especially renowned, knowledgeable people, sarpanches, progressive livestock farmers and elderly persons. A total of 64 informants, mainly residing in these hilly areas, were interviewed in the local language. They ranged in age from 37 to 78 years and were interviewed separately to obtain accurate information. Data were collected on the major livestock species in the area, size of flock/farm, major diseases, herbal and other treatments used, major plants/trees used, parts of plant used, plant byproducts used, technique to prepare the herbal medicine, application procedure, time and duration of treatment, recovery time and cost of treatment. The information obtained in the field was crosschecked with the literature available.

Results and discussion

Due to the rough terrain and poor transport facilities, local people consider ethnoveterinary remedies for livestock treatment to be most important in these hilly areas: 23 different ailments of livestock and their traditional treatments were identified and documented. The details of common ethnoveterinary remedies used along with the herb name, family name, local name, plant part used, mode of administration, disease condition, dose and recovery time are given in Table 1. Leaves (30%) were the most used, followed by whole plant and seeds (Fig. 1). The study showed a dependence of more than 70% tribal population on ethnoveterinary and herbal medication, whereas only 30% depended on allopathic or Western medication. A local veterinary doctor was consulted mostly in cases of complex disease conditions, surgery, dystocia or accidents. It was observed that traditional knowledge of herbal and local medicine still forms the first line of defence for treating livestock diseases. Milk, jaggery, butter, wheat flour and curd were the major vehicles used for administering medicines. Similar vehicles for administration were reported by Dilshad et al. (2009). These remedies were administered mostly orally and, in some cases, topically. The amount and doses were reported differently by all the respondents, indicating that there were no clear-cut standards for doses of these remedies. Also duration of treatment and response to treatment were not uniform, with different respondents reporting different treatment time and recovery time. Leaves, roots, fruit, flower, bulbs, seeds and stems were the commonly used parts of plants. Similar findings were reported by Abbas et al. (2002), Giday et al. (2003), Nfi et al. (2001), Ole-Miaron (2003) and Viegi et al. (2003).

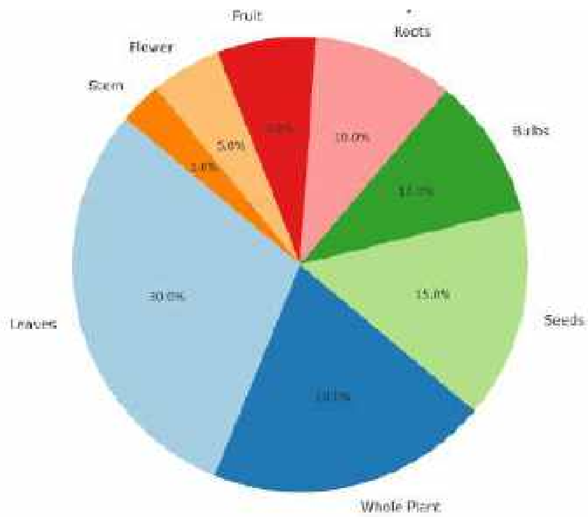

Fig. 1: Plant parts used

Farm size. Herd size varied from 2 to 200 animals. Large herds were mostly of sheep and goats. The most common ailments reported by the respondents in large farms/herds were indigestion, fever, stomach ache and allergy. In the case of cattle, most of the remedies were for bloat and tympany. Farmers with large herds preferred veterinary advice on a regular basis whereas farmers with smaller herds depended more on ethnoveterinary and homemade remedies. Farmers were also reluctant to take their livestock to a veterinary hospital and preferred the visit of a veterinarian to their farm.

Most common problems. The most common problems reported by livestock owners in these areas were bloat, tympany, indigestion, anorexia, diarrhoea, ecto-/endoparasites infection, fever, cough and allergy. Bloat, indigestion and fever were mostly treated using these local remedies. In case of ecto- and endo-parasitic infections, tribal farmers reported the use of antimicrobial drugs due to multiple parasitic infections and high resistance to other drugs and treatments. In the case of some surgical conditions like medial patellar desmotomy (MPD) or traumatic reticuloperitonitis (TRP), farmers depend on veterinary experts and did not rely on herbal remedies or local treatment. Similar treatments have been reported by Ishtiyak and Hussain (2017), Riyaz and Ignacimuthu (2023) and Tali et al. (2019) for treatment of indigestion, tympany and ecto- and endo-parasites.

Common remedies. The most common plants and plant byproducts used were *Trachyspermum ammi, Curcuma longa, Morus nigra, Aloe vera (L.) Burm. f., Trigonella foenumgraecum, Cannabis sativa, D.wrightii, Azadirachta indica, Thymus vulgaris L., Bambusabambos (L.) Voss, Allium cepa L.* Some of the plants were used for multiple treatments like pain, fever, indigestion, bloat etc. The most common plant families reported by respondents were *Apiaceae* and *Amaryllidaceae*. A few plants like *Allium sativum L, Allium cepa L, Trachyspermum ammi* and *Curcumalonga* were reported by 90% of respondents, indicating the trust and effectiveness of the ethnoveterinary practices used by tribal farmers. These remedies were used in treatment of multiple problems. Paste, crushed seeds and boiled leaves were the most preferred medicinal form used for administration. Similar results were reported by Dutta et al. (2022) and Khateeb et al. (2015). It was also observed that tribal people mostly trusted the easily available local household spices and herbs for treatment purposes.

Administration mode. Different methods of administration were used based on the plant type used and disease condition. The preferred method was oral, then topical for effective and fast results. The topical method was mostly used in case of injury, wound, allergy or inflammation condition. Chakale et al. (2021) reported similar findings of preferred oral route as faster compared to topical application.

Conclusion

The traditional ethnoveterinary system of treatment is the most trusted and important prevailing system in hilly areas of Jammu. It is more preferred in remote areas with poor availability of veterinary health services due to rough terrain. It is very important to promote cost-effective ethnoveterinary measures to control diseases in livestock. Ethnoveterinary practices are still used as the first line of defence by tribal people to control livestock diseases because of high production cost and resistance developed as a result of excessive use of antimicrobial drugs. It is very important to promote cost-effective ethnoveterinary measures to control diseases in livestock.

Analysing the Indigenous knowledge contributing to the survival of pastoralists in northern Kenya's dry areas

Kagunyu, A[1]; Wandibba, W[2]; Thuranira, E[1]

[1]Kenya Agricultural and Livestock Research Organization P.O. Box 57811, 00200, Nairobi.
[2]University of Nairobi, P.O. Box 30197 – 00100 Nairobi, Kenya

Keywords: Indigenous knowledge, survival, dry lands, natural calamities

Abstract

Pastoralists in Northern Kenya have relied on indigenous knowledge for centuries to endure natural disasters such as droughts, famine, floods, and diseases. This study aimed to examine the types of indigenous knowledge applied by livestock keepers in Northern Kenya and how these practices are influenced by climate variability. Guided by resilience theory, data were collected through secondary sources, semi-structured interviews, focus group discussions, and direct observation. The findings reveal that indigenous knowledge is crucial for survival in Kenya's dry areas including a deep understanding of local ecology, facilitating migration to greener pastures during droughts. Pastoralists select livestock species based on their adaptability to specific ecological conditions, enhancing survival rates. Indigenous knowledge is crucial for survival in Kenya's dry areas, encompassing a deep understanding of local ecology and facilitating migration to greener pastures during droughts. Pastoralists select livestock species based on their adaptability to specific ecological conditions, enhancing survival rates—Indigenous weather forecasting methods guide movement, showcasing the effectiveness of traditional knowledge in anticipating environmental changes. Additionally, pastoralists possess extensive knowledge of wild edible plants used for food during drought and employ indigenous food preservation techniques, contributing to food security and sustenance. These findings highlight the critical role of traditional knowledge systems in enhancing adaptive capacity and sustaining livelihoods during calamities. However, the efficacy of indigenous knowledge is eroding due to increasing climate and socio-economic challenges, emphasising the need for sustainable interventions. Integrating Indigenous knowledge into formal policies, conserving biodiversity, and promoting hybrid approaches combining Indigenous knowledge with modern technologies is crucial. Capacity-building, financing for herd restocking, and biodiversity conservation are necessary to safeguard livelihoods amid climatic and socio-economic changes.

Introduction

Pastoralism is a critical economic and cultural practice, particularly in arid and semi-arid lands (ASAL), sustaining millions of livelihoods globally (Wafula et al., 2022). In Kenya, ASALs constitute over 80% of the country, supporting 70% of the livestock and 36% of the human population (KNBS, 2019). These regions experience limited rainfall—arid areas receive 150–550 mm and semi-arid areas 550–850 mm annually (Schilling and Werland, 2023). Kenya's ASAL counties have faced increasing drought frequency, with inter-drought periods shortening from 5–10 years to 2–3 years (Nyaoro et al., 2016).

Erratic rainfall and growing aridity exacerbate the vulnerability of pastoralist communities, which rely heavily on mobile livestock production. Additionally, severe El Niño floods in 1961-62, 1997-98, and 2023-24 have caused widespread loss of life, displacement, and property destruction. Despite these extreme climatic conditions, pastoralist communities have thrived in these environments over generations by relying on indigenous knowledge systems and practices. Conventional modern technologies and interventions have not effectively mitigated these challenges, but indigenous knowledge has played a crucial role in resilience and survival. However, there is limited documentation and integration of this knowledge into current adaptation strategies, which could otherwise strengthen community resilience to climate extremes. This study was guided by two objectives; to identify the indigenous knowledge used by pastoralists to survive natural disasters; and to examine the constraints limiting the effectiveness of indigenous knowledge in building pastoralist resilience.

Methods

Research sites

This study was conducted in Marsabit County, focusing on the Dukana and Sololo areas. It specifically targeted the Gabra and Borana communities, which are the largest ethnic groups residing in the county.

Data Collection Methods

The study involved 200 households selected through purposive and simple random sampling. Participants were 160 males and 40 females. Data was collected through interviews, direct observation, and focus group discussions. Trained enumerators administered questionnaires covering natural disasters, indigenous knowledge, and barriers to its effectiveness. Direct observations assessed environmental conditions and natural resources, while separate FGDs for men and women were used which provided additional insights and data triangulation.

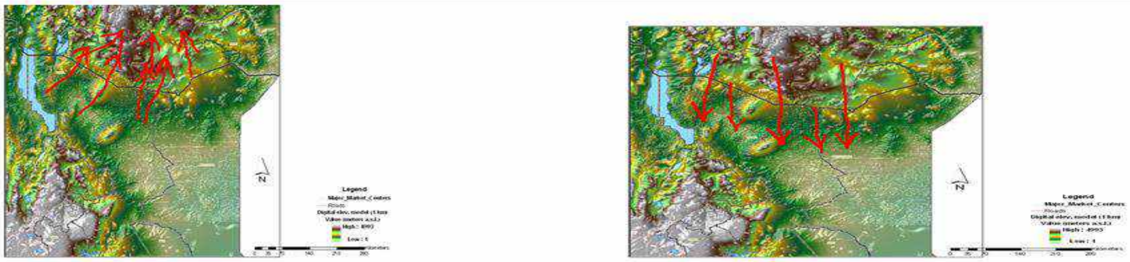
Data Processing and Analysis

Qualitative data were organized to align with the study objectives. Quantitative data collected from household interviews were carefully edited, coded, and entered into SPSS (version 28) for analysis. Descriptive statistics, such as frequencies and percentages, were computed to provide a comprehensive overview of the study findings.

Study Results

Seasonal Livestock Mobility

Seasonal livestock mobility is a crucial survival strategy for pastoralists in Northern Kenya, enabling adaptation to environmental challenges. *Badheessa Gannaa* (wet season migration) follows the first rains, with livestock moving to peripheral grazing areas, while dry season migration brings herds closer to permanent water sources, often crossing borders (see Picture 1). Before migration, elders send herders to assess range conditions in fall-back areas and negotiate access with local communities. Men migrate with the livestock, leaving women, children, and elders at the homestead.



Picture 1: Seasonal Migration of the Borana and Grabbras of Northern

Indigenous early warning signs of weather patterns

Pastoralists in Northern Kenya use various indicators to predict droughts. Black intestines in slaughtered animals were identified by 41% of respondents, hot temperatures by 16%, and tree leaf-shedding by 15%. Additionally, 12% noted bird sounds and movements, 11.5% referred to star positions, and 4.5% mentioned a clear, cloudless sky. Other signs given included female camels crossing their rear legs and urinating on their thighs, livestock restlessness and slow movement. Signs of impending rain include cattle shaking their rear legs, playful behaviour in bulls, livestock hesitating to enter their shed, the flowering of plants like Acacia *nilotica,* and specific star patterns.

Herd diversification by pastoralists

The Borana and Gabbras of Marsabit practice herd diversification, rearing camels, cattle, goats, sheep, and donkeys. This strategy optimizes ecological resource use, enhances food security, and increases resilience to drought, making it an effective adaptation to climate variability. Camels emerged as the most preferred by 72% of respondents for their resilience, high milk production, and medicinal benefits. Goats and sheep (22%) were valued for rapid reproduction and ease of restocking, while 4% favoured cattle for their market value. Poultry (2%) were kept for their low theft risk. Figure 2 gives details

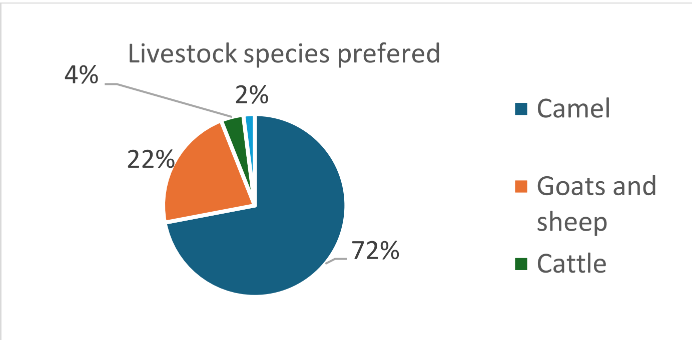


Figure 2: Livestock Species Preferred

Reliance on wild edible plants

Pastoralists in Marsabit rely on wild edible plants for survival during droughts and famines, with 86% of respondents affirming their use. Key plants for the Borana include Grewia tembensis (deka), Cordia gharat (mader), Zizyphus mauritiana (qurqura), Berchemia (jaj jab), Grewia villosa (ogomdi), and Lannea alata (kumude). The Gabra depend on Grewia spp., Carissa edulis, Balanites aegyptiaca (desert date), Adansonia digitata (baobab), and wild sorghum.

Indigenous ways of preserving foods among the pastoralists of Northern Kenya

Pastoral communities preserve meat and milk using indigenous traditional knowledge. Meat is cut into strips, sun-dried, deep-fried in animal fat, and stored in solidified fat in containers, known as enyas, opera, nyirinyiri, or koche depending on the community, lasting 6 months to a year. Milk is preserved by smoking gourds with Olea africana leaves, which act as natural preservatives, enabling the milk to remain consumable for extended periods, regardless of weather conditions.

Challenges affecting the efficacy of Indigenous knowledge
Challenges to livestock mobility

The study found that while livestock mobility is essential for Borana and Gabra pastoralists to access rangelands and share resources, climate variability, especially frequent droughts, has caused water shortages, depleted grazing, and conflicts. Migration routes up to 600 km expose livestock to harsh conditions, leading to deaths. Shared resources lead to overgrazing, feed shortages, and disease transmission, making this adaptation increasingly unsustainable under changing climatic conditions.

Barriers of early warning methods
Most households (75%) affirmed the reliability of traditional early warning methods, 14% believed they were only reliable in the past, and 11% deemed them unreliable. Focus group discussions highlighted that increasing climate variability and severity have reduced their effectiveness. Lwasa et al. (2017) attributed this decline to the disappearance of traditional indicators, cultural shifts, and evolving religious interpretations.

Barriers to herd diversification
Opiyo et al., (2015) emphasized that herd diversification is a vital long-term adaptive strategy for pastoralists in Northern Kenya, driven by livestock's varied drought tolerance. This is supported by Wako et al., (2017), who found that goats and camels are highly drought-resilient, efficiently utilizing poor-quality forage, while cattle and sheep suffer higher mortality due to their lower adaptability. Despite its importance the strategy faces barriers such as livestock losses from recurrent droughts, high restocking costs, degraded foraging resources, reduced labor due to schooling, and youth migration to urban areas, limiting diversification efforts.

Challenges of accessing wild edible plants
Pastoral communities have traditionally depended on wild edible plants (WEPs) during drought-induced famines. However, their availability has declined due to settlement expansion, restricted access to fenced areas, overharvesting for construction materials, overgrazing in conflict zones, and the spread of invasive species like *Prosopis juliflora*, which hinder the growth and accessibility of WEPs.

Challenges of Indigenous methods of storing food
Challenges affecting Indigenous food and milk preservation among pastoralists include poor hygiene in processing, leading to illnesses like diarrhoea, livestock losses limiting inputs, and droughts reducing food shelf life. Additionally, recurring droughts have depleted plants traditionally used to extend milk preservation, further impacting food availability and storage practices.

Discussion, Conclusions and Implications
Discussion: The study highlights the critical role of indigenous knowledge in sustaining pastoral livelihoods in Northern Kenya through adaptive strategies like livestock mobility, early warning signs, herd diversification, and reliance on wild edible plants. However, challenges such as climate variability, resource constraints, and socio-cultural shifts necessitate integrating indigenous knowledge with modern resource management and technological approaches for enhanced resilience.

Conclusion: Indigenous knowledge is vital for pastoralists' adaptation to climate variability, offering time-tested strategies for resilience. However, its efficacy is eroding due to increasing climate and socio-economic challenges, the need for sustainable interventions.

Implications: Integrating indigenous knowledge into formal policies, conserving biodiversity, and promoting hybrid approaches combining indigenous knowledge with modern technologies are crucial. Capacity-building, financing for herd restocking, and biodiversity conservation are necessary to safeguard livelihoods amid climatic and socio-economic changes.

Acknowledgement
We sincerely thank the Director General of KALRO, the Centre Director of KALRO-Biotechnology, and the participants for their invaluable support, guidance, and insights that ensured this project's success.

The science-policy adaptive capacity building for local herding and government groups to reduce climate vulnerability: case of Gobi-Altai province, Mongolia

Balt, S[1]; Khurel, N[2]; Bolor, K[3]

[1] International Cooperation Department, Mongolian Academy of Sciences; [2] Institute for Strategic Studies, Mongolia; [3] Sustainable development Institute for western region of Mongolia

Key words: Climate-pasture-livelihood nexus; pastoral vulnerability; climate adaptation; science-policy adaptive capacity (SiPAC)

Abstract

The effects of climate change and active use of natural resources are the key factors to pastoral social-ecological vulnerability in agriculture-based developing countries. Pastoral vulnerability is a base to measure how climate change affects pasture, livestock and the livelihoods of herding communities. It is explained by natural stressors and human factors of pasture use and vegetation cover change as a set of interlinked impacts on social and economic conditions and coping strategies of herder communities. Rural herding communities and local government units lack scientific information to better understand the nexus of Climate-Pasture-Livelihood and how it might impact their well-being now and in the future. They also have limited capacity building resources in science, policy, and its implementation. The science-policy adaptive capacity program (SiPaC) was implemented in Gobi-Altai province, Mongolia to build capacity of local herding communities, practitioners, and government units. The SiPAC served as a platform to facilitate knowledge, management, skills, networking, partnership and ultimately, formulation of local adaptation strategy of targeted stakeholders through scientific contributions, methodologies, training manuals, practical and interactive sessions tailored to local needs.

Introduction

In Mongolia, 57-70% of the local economy and 80% of total labour force in rural areas depend on animal husbandry (NSO 2020). The vulnerability of pastoralism is linked with natural stressors such as drought and zud (harsh winter condition) (Togtokh et al. 2014), human factors such as pasture use and vegetation cover change, the impacts on social and economic conditions and coping strategies of herder communities (Troy 2014). The western region of Mongolia, where Gobi-Altai province is located, is an arid, non-equilibrium environment with highly variable weather (Gomboluudev 2019) and affected by climate change related disaster extremes, water resources shortage, and cultural changes.

To effectively align adaptation policies and prioritise implementation measures, policy makers require comprehensive information obtained via vulnerability assessments of regions and various sectors (Benjamin et al. 2011). It is important for sustainable pasture use, pasture management planning, and the effective implementation of adaptive measures. Suvdantsetseg et al. (2020) found that local policy documents have ‘limited alignment’ with climate change responses, particularly inadequate adaptation measures adopted to strengthen social resilience. Gobi-Altai province has, indeed, not updated its development policy in accordance with Vision-2050, national development policy and global Sustainable Development Goals (SDGs). This finding revealed the urgent need to formulate new policies to align climate change adaptation and sustainable development at local level.

However, local governments have limited capacity to formulate science-based policy. Therefore, the science-policy adaptive capacity program (SiPaC), funded by Asia-Pacific Network on Global Change Research, was implemented in Gobi-Altai province. Building on the past pastoral social-ecological vulnerability assessment, the SiPaC program aimed at enhancing local herding communities, young leaders/researchers, practitioners, and government units to participate in, and connect to, local, national, and regional science and policy agenda (SDGs) on climate change adaptation and enable them to learn science-based pastoral management, best practices, and innovative solutions.

Methods

Description of study area. Located in the western Mongolia, Gobi-Altai is a sparsely populated province with total area of 141.1 thousand sq.km and a population of 58.4 thousand, 67 percent of whom live in rural areas and practice nomadic herding. The livestock sector, with its 3.8 million sheltered livestock generates 55% of the province’s GDP (NSO, 2024). The SiPAC was implemented in 5 sub-provinces (Biger, Bayan-Uul, Khaliun, Taishir, and Tugrug) of Gobi-Altai province (Figure 1).

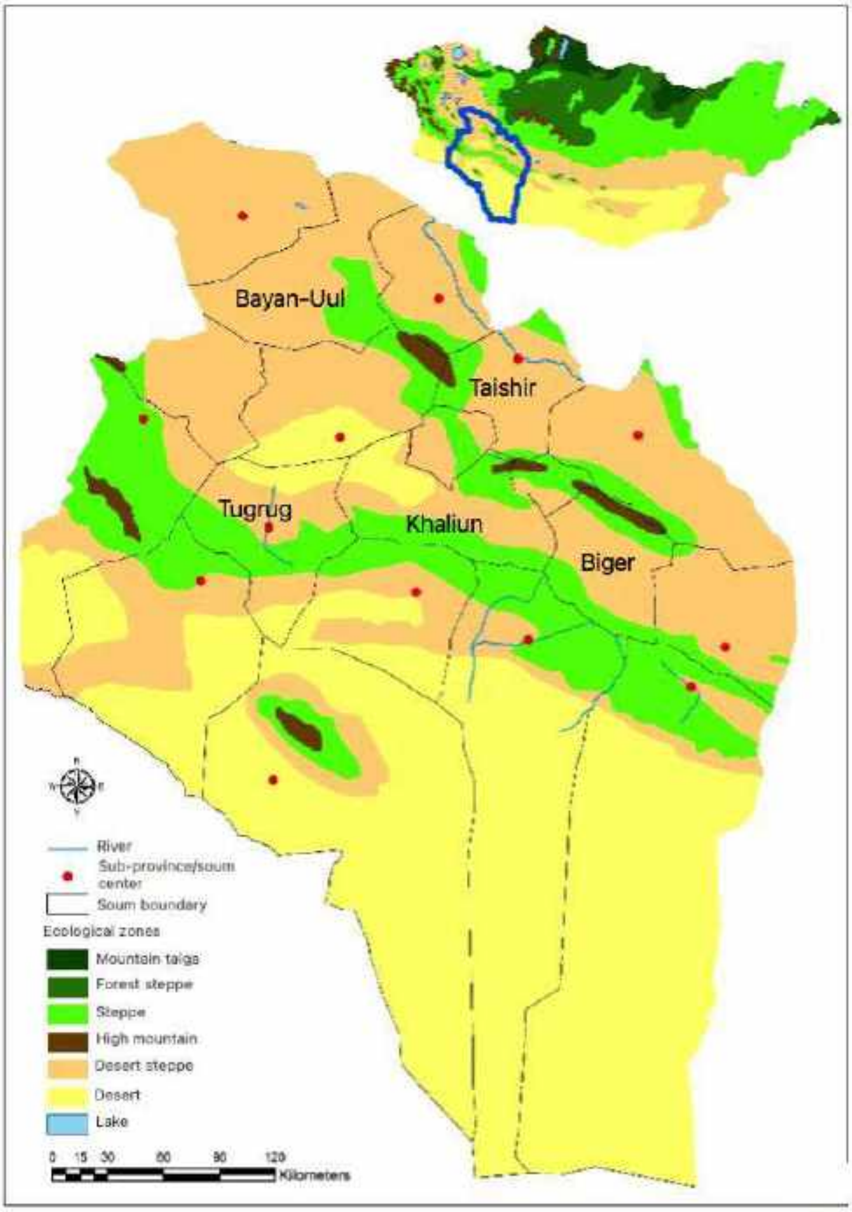

Figure 1. Location of study area.

The participants included diverse stakeholders of young leaders, herding communities, government officers, practitioners, and active persons, who were selected based on their interest, participation in problematic issues, and future contributions to the local development. The training used integrated training curriculum-based participatory approach through a variety of structured learning tools, methodologies including lectures, teamwork, leadership managements, and practical and interactive sessions to facilitate their knowledge, skills, formulation of local adaptation strategy or other documents, reduction of pastoral vulnerability and science-based pastoral managements. The interactive sessions provided theoretical presentations, lectures, and methodologies followed by exercises.

Results and Discussion

In total, five capacity building trainings were organized, each session was designed as a 2-4-day workshop to provide insights into specific topics including pastoral socio-ecological vulnerability assessment; local and national policy interrelation analysis; science-based policy training curriculum; and local strategic development plans. Trainings involved active participation by multiple academic researchers, policymakers, and representatives of rural herding communities, young leaders, and local government units.

There were pre and post-evaluation of the impact of training and feedback of trainees after the training was concluded.

Throughout the project period of two years, the representatives of five soums, Bayan-Uul, Biger, Taishir, Khaliun and Tugrug, learned about climate change and its effects on their environment, wellbeing and livelihoods, what strategies to implement to adapt and become more resilient against those adversaries, and did practical training on how to integrate adaptation strategy into local policy. As a result, the participants jointly developed the first draft of the adaptation strategy plan for their respective soums. In the final dissemination workshop, each team presented brief introduction of their draft strategy plan which would later be adopted by the respective local governments.

The SiPAC program was successful as it served as a platform to facilitate knowledge, management, skills, networking, partnership and ultimately, formulation of local adaptation strategy of targeted stakeholders through scientific contributions, methodologies, training manuals, practical and interactive sessions tailored to local needs.

Acknowledgements
We are grateful to APN for providing funding to support the project, and Mongolian Academy of Sciences and Governor's office of Gobi-Altai province for their kind support and assistance in organizing workshops.

Building a community of practice around the network of rural living labs of the Grassland Management project in Uruguay

Areosa Aldama, P; Pereira Machin, M; de Hegedus, P

Instituto Plan Agropecuario, B. Artigas 3802, Montevideo, Uruguay.

Key words: Community of Practice; Rangeland Management; Workshops; Living Labs; Learning

Abstract

Since 2021, the Grassland Management project has been monitoring 30 livestock farms (Living Rural Laboratories) grazing natural pastures. The objective of the project is to contribute to the better management of natural pastures, through the use of good pasture management practices, with the aim of developing sustainable livestock systems. After three years, 130 workshops have been held with the participation of laboratories, the accompanying group of neighbouring producers, the technicians responsible for monitoring and the extension agency. These meetings take place in autumn and spring, are attended by 15 producers (on average per laboratory), field visits are carried out and evaluations are made. Currently, a total of 1800 people are participating in project activities. From August 2022, on the occasion of the first meeting of the Laboratory Network, the Community of Practice on natural grassland management started to operate. According to the theory of Community of practice, the participants of the Community share a common concern, a set of problems, or an interest in a topic, and are motivated to fulfill both individual and group goals. Three levels of involvement are identified: 1) the central core (30 producer families and technical team; 80 people), 2) the accompanying core (15 neighbours per Lab. + 450 people) and 3) the peripheral core - a heterogeneous group composed of multiple actors, research and private technicians (+ 300 people). Based on the evaluation conducted within the framework of the project, through a survey of participants, it can be concluded that the learning of new concepts and ideas is a process that 90% of the participants have shown, the remaining 10% have incorporated new approaches to what they already knew. Community building is an emerging feature of the project, which has been enhanced by the development of information technologies. It is envisioned as an information scaling strategy and a space for sharing the experiences of livestock producers. When the project ends, it will face the challenge of sustaining itself and ensuring its sustainability.

Introduction

The Grassland Management project has yielded pertinent information and findings from the monitoring of 30 living labs, encompassing the majority of the country's agro-ecological zones. A conceptual model has been developed that involves five macro-variables that are determinants in grassland management. These variables are combined in multiple ways, demonstrating that grassland management is a complex phenomenon. The variability and diversity of grassland systems, the transmission of capitalised learning, and the direct effect of these factors on the sustainability of grassland enterprises are all key elements of this model. The implementation of self-assessment and quantification protocols enables the standardisation of processes. The project provided over 1,900 participants with a straightforward and reliable method of estimating available pasture (the index on food plate [FPI]), which serves as a decision-making tool. As an outcome of the process, the network of living laboratories is now conceptualised as a community of practice that is continuously evolving and intends to persist, facilitating knowledge acquisition (Areosa, P. et al., 2021) y (Pereira, M. et al, 2023).

Methods

A living lab is a space designed for interaction and collaboration, fostering creativity and problem-solving. It is a platform for cultivating critical thinking and knowledge acquisition among the individuals involved (Bravo-Ibarra, 2019). Such spaces facilitate the intersection of technologies and people in authentic contexts (Zavratnik et al., 2019). The term "laboratory" typically denotes a controlled environment with variables that can be manipulated. In contrast, the concept of a "living laboratory" suggests a more open and dynamic approach, where the laboratory is integrated into the real world and its inherent complexities. The defining aspects of living labs include the following: Real environment: In contrast to the controlled environments of traditional laboratories, living labs operate in real conditions, including factors such as climate, pricing, and specific circumstances. This enables the efficacy of solutions to be assessed in authentic contexts, which may present distinctive characteristics and challenges. Open innovation is promoted by these laboratories through the involvement of multiple actors, allowing for the contribution of different perspectives to the development of more appropriate and sustainable solutions.

The laboratories serve as spaces for dialogue and learning, facilitating exchange and the construction of knowledge through the workshop methodology. Joint creation is another key feature of living laboratories, which are based on the participation of the community in the creation of solutions. The members and participants of the laboratory are not merely subjects of study; they are also pivotal contributors to the advancement of knowledge and technologies (Areosa et al., 2024).

Results

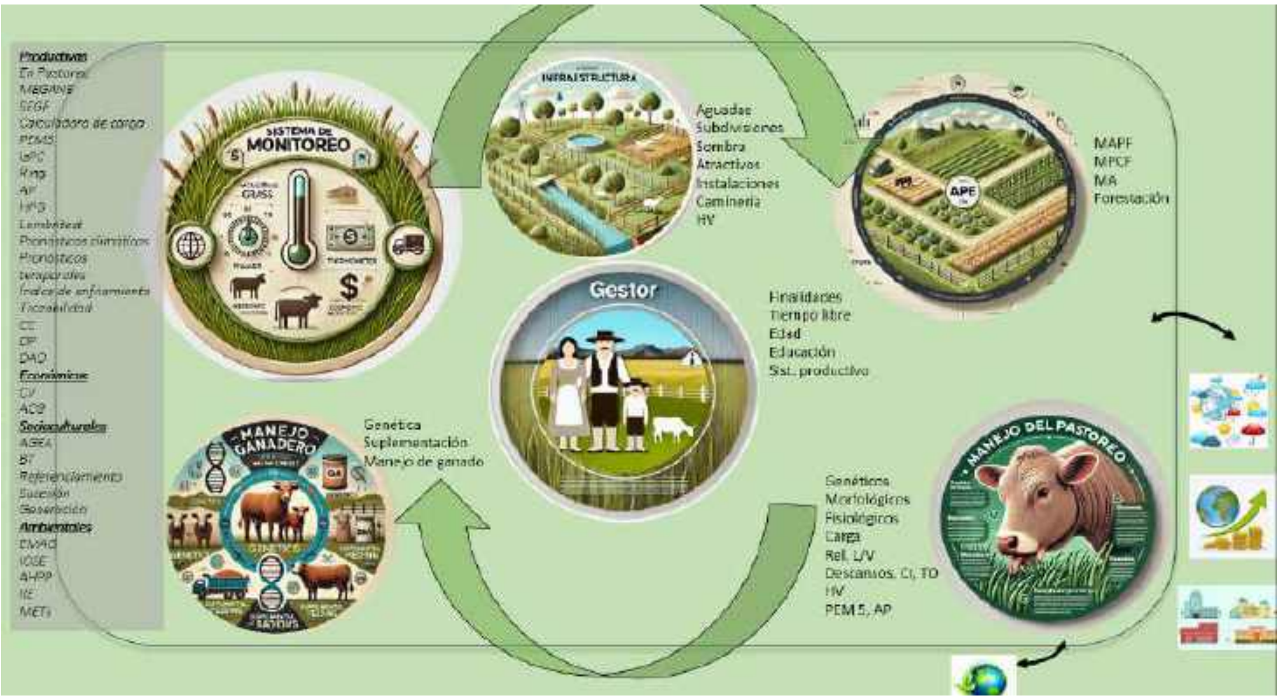

Figure 1. Conceptual model principal variables associated with effective pasture management practices.

The conceptual model generated by the project provides a systematic representation of the principal variables associated with effective pasture management practices. This product provides an evaluation framework for livestock producers, facilitating the planning and analysis of diverse scenarios and enabling prospective capacity and flexibility for adapting to changes. The macro-variables that warrant particular attention are: embeddedness in the context of infrastructure, the proportion of improved areas of strategic production, establishment ratio greater than 5 cm in the case of grazing management, strategic supplementation for livestock management and the importance of having a monitoring system in place. These approaches place an emphasis on process technologies and the soft skills (knowledge) of producers. In a complementary manner, the role of the natural field as a determinant of favorable environmental performance indicators is evident, providing systems with the resilience and resistance necessary to persist over time. The grassland management community of practice represents a learning community, comprising the living laboratory, dialogue workshop, and accompanying group components, which collectively form the laboratory network. This community demonstrates a capacity for synergistic and dynamic functioning, with learning outcomes that demonstrate a progressive improvement.

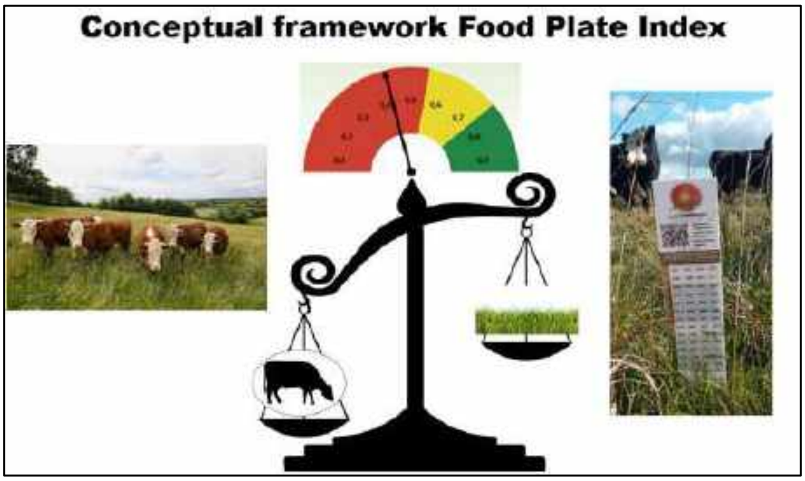

Figure 2. Food Plate Index method, proposed by the project and adopted by the 30 living labs.

Conclusions/Implications

The findings of the project substantiate the assertion that the long-term sustainability of livestock enterprises is contingent upon the macro-variables identified and their utility as self-assessment tools. These facilitate support, correction and the setting of new objectives, thereby enabling the construction of resilient family-business systems with adaptive capacity. This process, undertaken by each system, incorporates an appropriate degree of sophistication without compromising the fundamental simplicity, monitorability and protocolizability of the approach. In order to achieve this, it is necessary to promote reflective processes (critical thinking) that necessarily require a certain investment of time and motivation from decision-makers. This challenge is encountered in the process of extension, the development of learning and the acquisition of new skills, which undoubtedly represent one of the most significant impacts of this project.

Meal Plate Index: A simple and robust tool for decision making

Carriquiry, E; Duarte, E; Pereira Machin, M

Instituto Plan Agropecuario. Br Artigas 3802, Montevideo, CP 11.700, Uruguay.

Key words: forage planning, allowance, grassland, budgeting tool.

Abstract

Cattle and sheep production in Uruguay is mainly based on natural grasslands. Research has shown that most of the country is overgrazed, so it is important to work with higher grass allowances. A simple, robust tool has been developed that livestock producers can use to budget for feed, called the Meal Plate Index. It is based on the fact that each category of cattle requires a certain amount of forage according to the season and the cattle performance objectives to be achieved - these values have been determined by national research - and is compared with the availability of existing forage, which is estimated using a centimeter ruler - developed in an extension project - that relates grass height to dry matter content per unit height and animal performance. The two factors, the amount of grass available and the need for forage supply, are relate, and according to the result of the index, if the result is between 0 and 0.6, we are in a red zone, in danger and urgent decisions are needed; between 0.6 and 0.8, yellow zone of caution and possible short term decisions; 0.8 to 1.2, green zone, with no immediate need for management changes, and values above 1.2, brown zone, which can only be reached in spring and summer, and due to the fact that most species are C4, this surplus is of very poor quality. Several field days and courses have shown that the index is easy to understand, while its application is strongly conditioned by the fact that the grass should be measured at least every season. Any technology or method that facilitates the measurement or estimation of forage availability will facilitate the use of the index and result in better livestock performance.

Introduction

The lack of timely decisions on pasture supply, affected by climate variability, has a significant impact on the productive and economic outcomes of livestock systems. In Uruguay extensive livestock production based on natural pastures faces frequent droughts, that affect both production and the sustainability of livestock enterprises and their families.

Animal stocking, measured in livestock units (LSU), is used to calculate stress based on the surface area, but does not consider the actual availability of pasture at any given time, which limits its effectiveness. Studies such as that by Do Carmo et al. (2019) show that controlling feed supply improves results, but adoption is low, highlighting the need to involve livestock farmers in decision-making and monitoring.

The objective of this work is to promote the sustainable development of pastoral livestock farming in Uruguay through simple methodologies that facilitate technical change and co-innovation. To this end, an approach is proposed based on monitoring of pasture and animals, pasture diagnosis based on supply, evidence-based discussion and facilitation of adaptive decisions is proposed.

These elements seek to overcome the limitations of livestock systems, which are characterized by their complexity, combining biological components and family contexts, which makes efficient pasture management difficult in an uncertain and variable environment.

In particular, the aim was to develop a simple tool that covers all aspects of feed planning and can be implemented quickly and easily.

Methods

This work was based on the experience that led to the development of the Meal Plate Index (IsPC), Duarte et al 2023.

A total of 35 producers participated in this work, with a predominance of cattle farming systems and a wide variability in land area and resource provision. Initial workshops were held to level knowledge and develop a monitoring protocol. The variables monitored were, for pastures, height measured with a ruler and calculation of availability in kg dry matter (DM) and, for animals, weight measured with a scale and definition of grass requirements according to category. The IsPC, which relates grass supply to demand, was calculated using color-coded ranges: Red (<0.6:) Danger deficit), yellow (0.6-0.8): Caution, Green (0.8-1.2): Optimal, and brown (>1.2): Excess.

The strategies and analysis included the IsPC evaluation carried out in seasonal workshops with technicians and producers, the management strategies with UML diagrams that facilitated the interpretation and prioritization of measures such as sale of animals, deferral of feed, supplementation, etc. The scaling included the field days carried out with technicians and producers.

Dissemination included producer-led field days, on-farm support to new groups, training through workshops and courses, dissemination through articles, seminars and agreements, and the inclusion of the IsPC in national programs.

This methodological approach allowed us to analyze the heterogeneity between farms and to develop a scalable monitoring system that combines technical indicators with participatory strategies.

The methodological-technical framework used in the project was structured around three main pillars: estimation of feed availability, evaluation of animal needs and adjustment of the "diet plate" by calculating the IsPC. Each of these components is described in detail below: Estimation of forage availability:

- Measuring grass height with a ruler in different pastures.
- Convert of these measurements to kilograms of dry matter available per hectare.

Calculate of animal requirements:

- Evaluation of animal weight with a scale.
- Classification according to production category (breeding, rearing, finishing).
- Determine grass requirements based on these categories and production targets.

Adjustment of the "meal plate" (IsPC):

- The relationship between total grass availability and total system requirements.
- Classification according to diagnostic ranges (red, yellow, green, brown).
- Identification and prioritization of management action through participatory workshops.

This approach allowed for comprehensive management of feed and animals, providing producers with a clear diagnosis of the situation on their farm and the IsPC with a practical tool to optimize production based on forage available resources.

To estimate the amount of forage available, the use of a ruler was developed, calibrated and recorded (figure 1).

There is a relationship between the height of the mat and the amount of grass available. This relationship is established or calibrated by seasonal cutting. To do this, at least 30 seasonal cuts are made, looking for variability in height, where the height is measured beforehand and then varies by agro-ecological area and by season, as the structure of the mat changes.

Figure 1.- Ruler developed to estimate forage available

A basic thing to know before taking measurements is the grazing area. Measurements must be taken where the cattle graze, i.e. in the grazing layer, and avoid measuring things that are not part of the diet, such as bushes and shrubs. Pastures have what is known as plant heterogeneity, i.e. different plant communities. Measurements must be made in proportion to the size of each of these. Measurements are taken at the height of the densest layer, i.e. where the highest proportion of forage is concentrated.

It is defined as the kilograms of forage dry matter (DM) per kilogram of cow liveweight (LW) (kg DM/kg LW) and can be calculated for any pasture if we know how much forage there is per hectare and if we know the stocking rate in kg liveweight per hectare.

Forage supply = kg DM forage/kg live weight

Previous experiments carried out at the Faculty of Agronomy have led to the establishment of values of forage supply required by breeding cows in each season, while the rearing data have been constructed based on the results of experiments carried out at UFRGS (Brazil). The suggested values are related to the productive expectations of each category in each season of the year.

Table 1.- Forage supply values for different categories of cattle in different seasons of the year (Do Carmo et al, 2019).

	Offer kg dry matter/kg live weight			
Animal category	Spring	Summer	Autumn	Winter
Rearing up to 300kg	1 - 2	2 - 3	2 - 3	2 - 3
Finishing +300 kg	4 - 6	4 - 6	4 - 6	8 - 10
Breeding cows	More than 6	More than 6	More than 6	3 - 6

In this way, knowing the number of animals in each category, their weight and the amount of forage required (Table 1), it is very easy to calculate the amount of grass required per category and, by adding all the categories, the amount of grass that should be present on the whole farm at the time of monitoring.

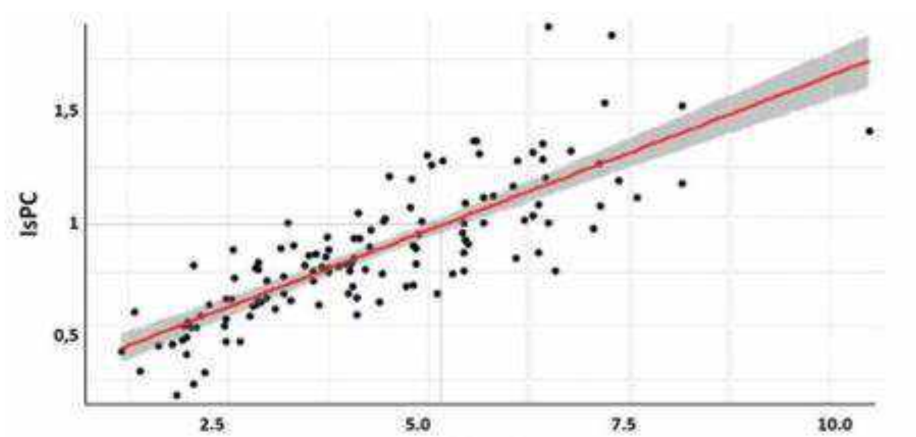
The IsPC is calculated by dividing the measured grass by the required grass (kg DM grass / kg DM required):

IsPC = measured grass/required grass and i.e. the result obtained is 0.96, it means that the meal plate is 96% full.

Results

In this work, grass height has a high positive correlation with IsPC (figure 2), which is a good single and simple indicator to estimate it, since this parameter depends mainly on the availability of grass and not on the needs of the animals.

IsPC = 0.143 * height + 0,233 (R^2 =0,65)



Height (cm)

Figure 2.- Regression graph between height (cm) and IsPC

Table 2. The following recommendations arise from the application of the IsPC:

IsPC	Color	diagnosis	suggestions
> 1.2	Brown	excess forage, loss of quality	adjustments to manage excess feed and loss of quality
0.8 – 1.2	Green	optimal, complete plate	no immediate need for management changes
0.6 – 0.8	Yellow	caution, targets at risk	short term possible decisions
< 0.6	Red	danger, animals at risk	urgent decisions required

Discussion

By working for several seasons with producers and their families, who seasonally monitored pasture and livestock, calculated the IsPC on their farms and discussed alternatives to adapt to the situation, we were able to develop a simple and effective methodology so that each producer, accompanied by other producers and their technician, could identify and choose the best decisions to make.

The IsPC was an indicator designed in a participatory manner and is important for monitoring and adjusting the relationship between availability and demand for pasture, based on the seasonal objectives of each category. It is important to mention that to calculate it, it is necessary to measure the height of the pasture. This fact is fundamental to quantifying the availability of food to be distributed in the "meal plate" of the pasture. It is also interesting to note that the IsPC is directly related to the height of the pasture.

The scaling up and dissemination of the IsPC tool has developed the lessons learned:

- Producers' experiences of monitoring, IsPC construction and workshops were shared at field days to demonstrate the overall methodology and results.
- Three-day courses have been held, with the aim of developing the capacity to take the necessary measures to establish the IsPC and to identify measures to maintain the IsPC.

The difficulties in scaling up arise from the fact that it is a technology that involves the implementation of group spaces that create, and then reflect on, an objective index to identify appropriate management practices. It is necessary to adopt practices to measure pasture and livestock (the culture in this regard is insufficient) to then identify appropriate management practices according to the IsPC which relates the available forage to required forage.

Conclusions/Implications

Despite the challenges of scaling up IsPC with a necessary cultural shift towards systematic measurement, its implementation offers a valuable decision-making tool for producers. IsPC improves pasture and livestock management, ultimately contributing to more efficient and sustainable agricultural practices.

Rangeland monitoring can engage graziers

Hough, B[1]

[1]Department of Primary Industries, Queensland. 9-15 Langton Street, Garbutt, Queensland 4814

Key words: Extension; Pasture; Burdekin

Abstract

Long-term monitoring is critically important in understanding how rangelands change across time in response to climate and management. In Queensland, the state-wide monitoring system called QGraze was established to monitor long-term pasture condition. The system has not only provided an opportunity to detect change in rangeland condition, but also engage with and build capacity with land managers in the livestock industry.

Beginning in 1991, the Queensland state Department of Primary Industries (DPI) in collaboration with land managers, installed nearly 450 sites on grazing lands across the state. Since then, these sites have been used by several projects to help inform the current state of rangeland condition and trends, such as monitoring the spread of the exotic grass *Bothriochloa pertusa* in the Burdekin district in North Queensland.

Just as importantly, enhanced engagement with graziers occurs as a result of surveying QGraze sites on their properties. This allows for the collaborative sharing of information and knowledge between DPI staff and the local grazing community. Graziers are interested to learn about their pasture and land condition in finer detail and the changes over time. The subsequent discussion regarding the contributing factors is valuable to inform their management decisions. Given the long timeframe over which monitoring has occurred, these conversations often span multiple generations, managers, and seasonal conditions. In turn, DPI staff are provided with perspective and context around the factors contributing to rangeland condition.

Due to the dedicated maintenance and monitoring of the sites by staff, QGraze provides a valuable resource for a combined understanding of the natural resource base underpinning Queensland's grazing lands.

Introduction

Native pastures provide the feed-base for a vast section of Queensland's grazing industry (ABARES, 2024). They also provide vital ecosystem services, and their management impacts major downstream ecosystems like the World Heritage Listed Great Barrier Reef – (GBR). Unfortunately, there is evidence of declining land condition through overgrazing and lack of resting (Gardener *et al.* 1990; McKeon *et al.* 2002). This includes declines in ground cover, loss of perennial grasses, invasion by the exotic *B. pertusa* and woody thickening, e.g., of the shrub *Carissa ovata* (currant bush)(De Corte *et al.*

1991; Rogers *et al.* 1999). Long-term monitoring of this native pasture resource is thus crucial for maintaining sustainable grazing land management and for the health of important ecosystems. Much of Queensland's grazing lands incorporate large spatial heterogeneity and are subject to high rainfall and climate variability within and between years (O'Reagain et.al., 2014). Detecting and interpreting temporal changes in the state of grazing lands can be difficult. While some changes in pastures are drastic, for example following fire, others are more subtle, such as the gradual loss of key perennial grasses or woody thickening and are less obvious to land managers. Furthermore, the recollection of past conditions can be subject to several cognitive biases which can lead to a misrepresentation of actual events (Roediger & Butler, 2011). Monitoring provides an objective record which helps to track changes in pasture composition and ground cover, identify trends in species diversity, and assess the overall health of vegetation.

Method

The Queensland Grazing Land Monitoring Project (QGraze) was established by the then QDPI in the early 1990's to implement a program to monitor change in condition across Queensland's grazed rangelands. At the time it aimed to provide a contribution to the National Rangelands Monitoring Program (Queensland Government, 2005). Nearly 450 permanent monitoring sites (Figure 1) were installed across a range of vegetation types and pasture communities. Sites are 4-hectare and consist of five 200m transects, spaced 20m apart, with each transect marked with a permanent centre peg. Twenty evenly spaced quadrats (0.25m²) are assessed along each transect, recording pasture species frequency, and estimates of ground cover and tree canopy cover. At each site 100 assessments are made along a series of 200m transects, recording pasture species frequency, and estimates of ground cover and tree canopy cover. Broader site estimates of soil condition, biomass and relative contribution to the biomass from the most dominant species are also recorded. Set point photos are taken, and tree basal area is calculated using a dendrometer.

Figure 1: Distribution of QGraze sites across Queensland.

Following the survey, data is processed and stored on a central data server. A report is also shared with the grazier giving the frequency of the main species, the condition of the site, comparisons with previous assessments and images from the fixed transect markers.

Results

QGraze in the Burdekin region.

The Burdekin River in NE Queensland has a catchment of approximately 140 000 km2 and is one of the main sources of sediment to the GBR lagoon (Furnas, 2003). Nearly 100 sites were installed in the catchment, with surveys first conducted from 1992 onwards. During this decade many sites were surveyed up to three times, however during subsequent decades monitoring frequency declined, due to changes in funding and government priorities. In 2014 several sites were re-surveyed as part of a project focussed on the spread of the exotic stoloniferous grass *B. pertusa* (Stacey, 2014). With the purpose of adding to the understanding of *B. pertusa* spread, several properties were re-surveyed in 2020/2021 while a further 10 properties were surveyed in 2024 as part of the DPI's Reef Water Quality Grazing Extension Service. Despite the intervening 25 years since two of these sites were surveyed, both were intact, and the owners/managers of both properties knew the location of the site. This was despite one of the properties changing ownership during the period. This suggests that these monitoring sites are valued by the graziers. The 2024 survey sites represented a range of properties, which were managed by the owners, or employed managers, and some properties had changed ownership, including through family succession.

Understanding trends

Besides the site report that a grazier receives, district comparisons over time can also be made, giving both an indication of the influence of seasonal conditions and relative trend of the condition of that site. This contributes to a shared understanding of the rangeland condition across a district and the impact of an individual grazier's management. For example, a comparison of the change in the frequency of the pasture grasses Indian couch (*B. pertusa)* and Black Spear (*Heteropogon contortus*) across seven properties within a district showed trends which suggest the influence of prevailing broader seasonal conditions (Figure 2).

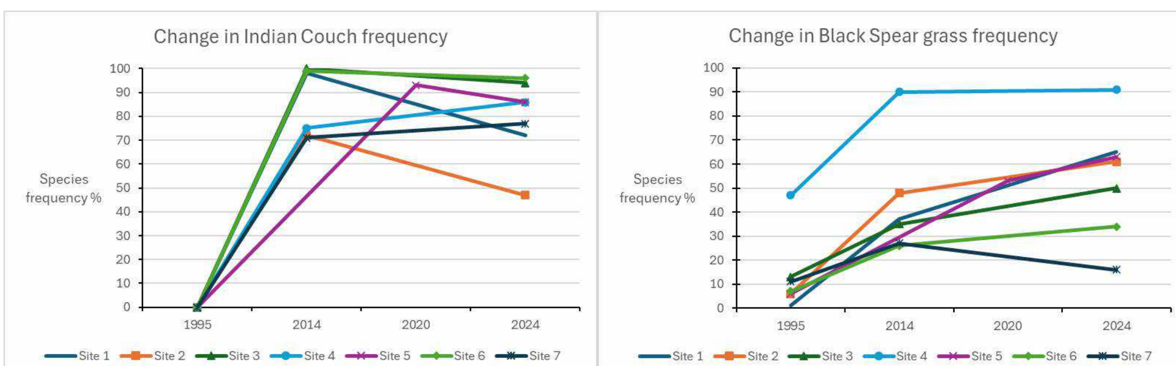

Figure 2: The change in frequency of Indian couch and Black Spear grass across seven sites on the same land type/pasture community with a maximum distance of approximately 80km between sites.

In 1995 Indian couch was not detected at any site but they all experienced a rapid increase by 2014 (or 2020 for site 5) and then all but two declined in frequency again between 2014 and 2024. Similarly Black spear grass increased at all sites between 1995 and 2014/2020 and maintained this increase in all except one site between 2014 and 2024. Similar patterns across these properties which varied in management systems suggest that seasonal conditions are an important factor in the spread of Indian couch.

Discussion

Sustaining Relationships

A fundamental component of DPI's delivery of extension services to the grazing industry, is placing the grazier at the centre of the activity and working *with* them to build capacity (Williams et.al, 2020). The installation of permanent monitoring sites on-property helps relate the science that QDPI does, to the grazier's own circumstances and decision-making. During the 2024 round of surveys, each visit was preceded by a conversation with the grazier discussing the site. Invaluable context for the site was given by the grazier during these conversations, such as history of fire, sown pasture species, and infrastructure development. Often the conversation would expand to include wider property and industry themes. On many occasions the grazier could recall the officers who installed the sites. These conversations were particularly beneficial for new extension and technical officers. Not only did they provide historical context, but also indicated to DPI officers what issues were important and what events may have been formative to the grazier's land management practices.

Industry capacity

The follow up report also provides an opportunity to continue and expand the relationship – allowing DPI staff to provide feedback on how sites have changed, place the results in a wider regional context and share the experiences of other graziers. Sometimes this can provide confirmation for a grazier that their management systems are achieving desired land condition outcomes. It can also initiate further discussion and an introduction to the range of DPI extension services. Customised support can follow, which addresses the multiple aspects of managing a beef business while building as broader professional relationship.

QGraze sites provide a sustained reason for ongoing, meaningful engagement between DPI staff and graziers. This interaction helps preserve and transfer corporate knowledge, ensuring that valuable expertise and historical context are not lost amidst staff movements, changes in ownership or generational transitions. DPI investment in this multi decade engagement enhances trust and promotes informed decision-making, ultimately supporting the long-term resilience and productivity of land management practices.

Conclusion

QGraze has provided a unique opportunity to objectively track changes in Queensland's grazing lands spanning multiple decades. Monitoring these sites has developed the technical skills of QDPI staff and given new officers the chance to connect with multiple generations of the grazing community. Effective agricultural extension is built on valued, trusted relationships – QGraze offers the chance to further develop these relationships and support practice change.

Acknowledgements

Thank you to the landowners in the Burdekin district for maintaining the sites and allowing ongoing monitoring.

Thank you to current and former DPI staff who see the benefit in this long-term data set, particularly Madonna Hoffman for managing the dataset.

2024 monitoring was conducted as part of the DPI's Reef Water Quality Grazing Extension Support funded through the Queensland Government Reef Water Quality Program.

Beyond grasslands: valuing the societal contributions of India's rangelands and pastoral systems

Hussain, S; Narula,V

Department of Social Work, Jamia Millia Islamia, New Delhi, India

Key words: Himalayan rangelands; socio-cultural contributions; ecological significance; pastoral systems.

Abstract
Rangelands and pastoral systems in India have traditionally been viewed primarily through the lens of livestock production, often overlooking their broader societal contributions. India's rangelands, particularly those nestled in the high-altitude Himalayan regions, are much more than mere grazing lands; they are lifelines for pastoral communities like the Chopans and Gujjars and are crucial to the country's ecological and cultural fabric. The rangelands of Jammu and Kashmir, Himachal Pradesh and Uttarakhand, with their rich biodiversity and fragile ecosystems, play a pivotal role in maintaining ecological balance. They support a unique form of pastoralism, where traditional practices have evolved in harmony with the environment, ensuring the sustainable use of these landscapes. Beyond their ecological significance, these rangelands are reservoirs of indigenous knowledge and cultural heritage, sustaining communities that have thrived in these challenging terrains for centuries.

This paper highlights how these landscapes contribute to food security through livestock rearing, support biodiversity, regulate water cycles, and sequester carbon, thus playing a crucial role in mitigating climate change. The research presents compelling case studies from Himalayan region, demonstrating how traditional pastoral systems have preserved these rangelands but and enhanced their resilience to environmental changes.This novel perspective underscores the need for holistic valuation methods that capture the dynamic interplay of ecological,economic, and cultural dimensions, paving the way for more sustainable and equitable rangeland governance and social cohension.

However,these vital landscapes are increasingly under threat from land-use changes, climate variability, and the marginalization of pastoral communities in policy-making. This paper advocates for a more inclusive approach to valuing rangelands,recognizes their full societal contributions and integrates them into national and regional development strategies.It seeks to influence policy frameworks that will ensure the sustainable management of rangelands by safeguarding them for future.

Introduction

India’s rangelands have traditionally been associated with livestock grazing while this perspective underscores their role in food production. It fails to capture their broader societal, ecological, and cultural contributions. In regions such as Jammu and Kashmir, Himachal Pradesh, and Uttarakhand, rangelands support biodiversity, sustain pastoral livelihoods, and maintain ecological processes that benefit society at large (Sharma et al. 2003). Communities such as the Gujjars, Gaddi and Chopans have practised pastoralism for centuries, adapting to the challenges of these fragile landscapes while maintaining sustainable resource use (Ingty 2021). In order to manage rangelands sustainably and guarantee that they continue to offer vital resources and services (Singh et al. 2021), this indigenous knowledge is crucial. Livestock rearing is a primary livelihood activity for millions of people in India, contributing to household income and local economies (Mitra 2013). However, land-use changes, climatic unpredictability, and the exclusion of pastoral voices from policy-making processes pose growing risks to these crucial ecosystems. According to Roe et al. (2009), rangelands have deteriorated as a result of pastoral communities' absence from land-use planning and decision-making procedures.

This study seeks to shift the narrative surrounding India’s rangelands from a narrow focus on livestock production to a holistic valuation that encompasses ecological, cultural, and economic dimensions. By drawing on case studies from the Himalayan region, it aims to demonstrate the multifaceted contributions of rangelands while advocating for policies that secure their sustainable management. Through the use of customs and traditions that have accumulated over the ages, pastoral societies like the Chopans and Gujjars have established complex interactions with these environments. This is something that requires attention to study these areas more. In India, rangelands especially those found in the high-altitude Himalayan regions have long been underestimated for the contributions they provide to society, frequently being relegated to the status as animal grazing areas(Bhasin 2011). This limited viewpoint ignores the many functions these landscapes perform in sustaining pastoral communities, safeguarding cultural legacy, and ensuring ecological equilibrium. In addition to being essential for raising cattle, the rangelands of Jammu and Kashmir, Himachal Pradesh, and Uttarakhand are also important ecosystems that support biodiversity, and control water cycles, all of which help to slow down climate change(Wagner 2013).

Methods

A qualitative approach was employed to understand the ecological and societal contributions of rangelands: that includes literature review related to the published studies on biodiversity, carbon sequestration, and water cycle regulation in India’s rangelands that provided a foundation for this research. Along with that case studies to document examples from the Himalayan regions of Jammu and Kashmir, Himachal Pradesh, and Uttarakhand are analyzed to illustrate the diverse contributions of rangelands while highlighting the interplay between traditional pastoral systems and rangeland sustainability. Interviews and focus group discussions with Gujjar and Chopan pastoralists were conducted to capture indigenous knowledge and cultural practices.

Results

Rangelands here serve as vital ecological corridors, linking fragmented habitats and supporting diverse species. Pastoral practices, that surprisingly involving almost every member of the family without any discrimination on the behalf of age,sex,gender , such as rotational grazing, enhance ecosystem resilience by allowing vegetation to recover and reducing soil erosion. Carbon sequestration potential in grassland soils is substantial, contributing to climate change mitigation. Additionally, these landscapes play a critical role in hydrological cycles, facilitating groundwater recharge. Rangelands also play a crucial socio-economic role, especially for marginalized communities like the Gujjars, Chopans, and other pastoral groups in India. These communities depend on rangelands for their livelihoods, and the services provided by these landscapes form the backbone of their economic activities. Rangelands are integral to the livelihoods of pastoral communities, providing grazing resources for livestock that sustain local economies which in turn will help sustain the national economy. These communities contribute to food security through the production of dairy, meat, and wool. Furthermore, the migratory routes and seasonal camps of pastoralists preserve traditional knowledge and foster social cohesion within and between communities.

The results highlights that women's involvement in pastoralism often extends to decision-making processes about herd management and land use. In some cases, especially in Uttarakhand, women may also take on leadership roles in community-level governance of rangelands, advocating for sustainable practices and mediating conflicts over resource use. However, despite their significant contributions, women there often face gender-based discrimination and limited access to resources and decision-making power.

Rangelands contribute to the broader rural economy by providing resources that support secondary industries, such as handicrafts and local markets there in addition to the direct income and livestock products, livestock by-products, such as hides, wool, dung, and manure which are valuable. In many rural areas, cow dung is used as a source of fuel, while wool from sheep and goats is used in weaving industries. Nonetheless, the problems of direct access to market, value-chain and intermediaries were reported. Seasonal movement between different grazing areas allows pastoral communities to optimize grazing and prevent overgrazing in any single area. Mobility was found to be a helping hand to creates economic linkages between different regions, with pastoralists engaging in trade, exchanging livestock, wool, and other goods as they travel. So,this way mobility has provides social benefits too, as it fosters inter-community connections and collaboration, which can help with managing common resources and resolving conflicts but it also creates conflicts too.

As the results supported the Dangwal(2009), rangelands of the Himalayan regions, hold significant cultural value for the communities that depend on them but some are started to settle down in one place or chose to be less mobile in terms of frequency. These landscapes are not only resources for livelihood but also integral to the spiritual, social, and traditional practices of pastoralists. Rangelands in Uttrakhand and Himachal often host sacred spaces, such as temples, shrines, and sacred groves, which are considered vital for the spiritual life of pastoral communities, however, Kashmir is exception. For example, in the Himalayan regions, sacred groves are protected areas within rangelands where the community believes that natural spirits dwell. These groves are not only areas of biodiversity conservation but also sacred spaces that influence local religious practices and social norms. These cultural practices help reinforce the connection between the community and the land. Additionally, social identity is often tied to the practice of pastoralism. The deep knowledge of rangeland ecosystems and livestock management is passed down through generations, shaping a community's sense of identity and belonging. Indigenous knowledge systems play a central role in the cultural aspect of rangeland use. pastoral communities includes knowledge about animal behavior, grazing cycles, plant species, and weather patterns. In the context of rangelands, this traditional knowledge enables communities to adapt to changing environmental conditions, optimize grazing, and manage the health of both livestock and landscapes. This knowledge is often codified in cultural practices, local governance structures, and community-based management systems that promote the long-term health of rangelands.

Discussion

The findings reaffirm the multifaceted value of India's rangelands, extending beyond their utility as grazing lands. Traditional pastoral practices exemplify a model of sustainable land management, balancing productivity with ecological health. These practices have evolved in harmony with the environment, ensuring the resilience of both human and natural systems. Culturally, rangelands house sacred sites and pilgrimage routes, reflecting their spiritual significance and their consideration of herd as a member of family is show their sense of belongingness. Rangelands also serve as reservoirs of indigenous knowledge, encompassing animal husbandry practices, medicinal plant usage, and ecological stewardship strategies even young members of communities understand these things. This knowledge, if leveraged, can inform contemporary conservation and development policies. Not only this but also empowering women in these communities can enhance the effectiveness of rangeland management and contribute to overall socio-economic development. However, the degradation of rangelands due to unsustainable agricultural expansion, infrastructure development, and climate change poses a significant challenge. Policy frameworks that prioritize industrial and urban development often marginalize pastoral communities, leading to the erosion of traditional knowledge and land-use practices. To safeguard these landscapes, a paradigm shift is needed in how rangelands are valued and managed. This includes:

- Integrating rangeland conservation into national climate adaptation and biodiversity strategies.
- Establishing participatory governance models that empower pastoral communities in decision-making processes.
- Promoting research and development initiatives focused on sustainable pastoral systems and rangeland restoration.

The societal contributions of rangelands ranging from food security and biodiversity conservation to cultural preservation highlight their importance in achieving sustainable development goals. Weber et al. (2004) argue that pastoralists possess detailed knowledge of their environment, which is crucial for sustaining their livelihoods and maintaining ecological balance. It also elaborates on the cultural and socio-economic functions of rangelands, providing deeper insights into their importance beyond just ecological roles while recognizing and enhancing these contributions is crucial for fostering resilience in the face of environmental and socio-economic challenges. However, rangelands also contribute to the broader national economy in ways that are often undervalued in conventional economic assessments. The cultural and socio-economic functions of rangelands are central to the livelihoods of pastoral communities in India. Rangelands not only sustain food security and economic productivity but also preserve rich cultural traditions, social identities, and community ties. The integration of indigenous knowledge and sustainable practices is essential for maintaining these functions in the face of challenges such as climate change, land-use pressures, and socio-political marginalization. Understanding and valuing the full spectrum of cultural and socio-economic contributions of rangelands is crucial for developing policies that ensure their conservation and the continued well-being of pastoral communities. According to Fernandez-Gimenez (1999), such religious connections to the land help ensure its sustainable management as the communities perceive themselves as guardians rather than exploiters of these spaces. Although rangelands are essential to rural economies and the environment, policy discussions have frequently overlooked their governance. The study highlights the need for more inclusive and participatory governance, arguing for policies that incorporate pastoralists' traditional knowledge into land management frameworks and acknowledge their rights. These regulations need to encourage sustainable grazing methods and guarantee that pastoral communities are involved in rangeland resource management.

Acknowledgements
The authors extend their gratitude to the pastoral communities of Jammu and Kashmir, Himachal Pradesh, and Uttarakhand for sharing their knowledge and experiences. Special thanks are due to my mother (Anjum Bano Rizvi) and my guide (Prof. Vani Narula) for their blessings, support and invaluable inputs.

The role of pastoralists' indigenous knowledge in managing South African mesic and semi-arid rangelands

Ntombela, K[1,2]; Samuels, I[1,2]; Finca1, A[1]; Engelbretch, A[2]; Zondani, T[1]

Key words: Knowledge co-production; Rangeland management; Pastoralism

Abstract

Rangeland management decisions by pastoralists are largely based on experiences which include but not limited to ecological relationships, animal health and land use practice. Recent droughts have stretched the natural resources, management skills and the livelihoods of pastoralist to their utmost limits. The aim of this research was to gain a better understanding of how pastoralists in the semi-arid and mesic rangelands utilize indigenous knowledge in their rangeland management. Face-to-face interviews were conducted to establish how South African pastoralists incorporate indigenous knowledge in their rangeland management and monitoring. Data obtained from the interviews was analysed using content analysis. Insights that emerged from the analysis included categorizing the rangeland by using such as vegetation and livestock indicators. Vegetation indicators included plant colour, plant diversity and abundance; while livestock foraging time and livestock health were livestock indicators. In order to allow rangeland recovery, interviewed pastoralists in the mesic rangelands detailed to divide the rangeland into '*soet veld'* [characterised by palatable grasses that have low fibre content and maintain their nutrients in the leaves throughout the winter] and '*suur veld'* [characterised by unpalatable grasses that have high fibre content and tend to remove their nutrients from the leaves during winter], which are utilized by livestock during different seasons. In the semi-arid regions, pastoralists practice transhumance between different vegetation types; while allowing rangeland recovery in the grazed area. Pastoralists also explained to incorporate western scientific knowledge with their indigenous knowledge to modify their grazing practices in order to minimize overgrazing and rangeland degradation. Therefore, this study emphasizes that movement towards sustainable rangelands requires transdisciplinary methodologies for an improved understanding of pastoralists' knowledge and management practices of their local rangelands.

Introduction

South African rangelands cover approximately 80% of the country's land surface (DAFF 2018). A large portion of livestock farming in the country occurs in arid or semi-arid rangelands that are vulnerable to climatic variability and climatic changes. Therefore, management of rangelands need to simultaneously consider the demands of various threats.

Pastoralism is an ancient livestock production system that was developed 7 000 years ago in response to long-term climatic changes (FAO 2018). Any decision by pastoralists is based on various knowledge which include ecological relationships, natural resource management, animal health and land use practice. According to Thomas et al. (2020), movement towards sustainable agricultural production is centred on an improved understanding of pastoralists' knowledge and learning processes. Insights on how a pastoralist understands their farming environment, and knowledge encounters between pastoralists are all crucial for pastoralists' knowledge assessment (Reed et al. 2010). Therefore, the aim of this study was to gain a better understanding of how South African pastoralists utilize indigenous knowledge in rangeland management.

Methods

This study engaged qualitative research focusing on multiple case studies, as described by Meredith (1998). Semi-structured interviews were used to investigate pastoralists' agro-ecological knowledge utilization in rangeland management. Pastoralists chosen for the study were goats, sheep and cattle herders. A total of 17 and 27 pastoralists from the mesic and semi-arid rangelands respectively formed part of this study. Mesic and semi-arid rangelands were represented by pastoralists from the Eastern Cape Province, and the Northern Cape Province in South Africa, respectively. Questions for the interviews were related to grazing lands utilization, and indicators used to monitor rangeland condition. Content analysis as described in Braun and Clarke (2012) was used to analyse data.

Results

Indicators used to monitor rangeland condition

Good rangeland: Grazing areas which visually appear to have a bright green colour were described as good rangeland condition in both study sites. Plant species such as *Pentzia incana*, *Limeum africanum* L. subsp. *africanum*, *Vachellia karroo*, Scutia myrtina, *Olea europaea* L. subsp. *cuspidat*e, *Portulaca oleracea*, *Themeda triandra*, *Cynonodon* sp., *Cenchrus clandestinus* and *Digitaria eriantha* were listed as indicators of good rangeland condition. Pastoralist emphasized the need for continued monitoring of such palatable plants to reduce degradation and overgrazing.

Poor rangeland: Pastoralists in the semi-arid rangelands explained that decreases in palatable shrubs such as *Didelta spinosa* and *Eriocephalus ericoides* indicate a poor grazing area. The high abundance of unpalatable shrubs such as *Tylecodon* sp., *Solanum elaeagnifolium*, *Opuntia aurantiaca* and *Euphorbia ferox* were listed as indicators of poor rangeland condition. One pastoralist reported to use foraging time as an indication of rangeland condition.

"*I usually let my animals out in the morning on their own without a herder, and they normally return to the homestead around 4pm. However, if this time passes and the livestock is not back, it is normally an indication that something is wrong or they have not eaten enough, meaning that the condition of the veld is bad. Then I either send out my herder to go and investigate the matter or I go myself*".

Use of indigenous knowledge in rangeland management

Pastoralists in the mesic rangelands described to improve rangeland condition by making use of livestock to spread *Themeda triandra* seeds through faecal matter. Pastoralists also described to alternate cattle grazing with goats and sheep grazing to utilize different grass heights in the rangelands. However, pastoralists emphasized the importance of continued monitoring for plant height to reduce root damage.

Livestock handling was described to be an important aspect of rangeland condition. A pastoralist in the mesic rangeland, detailed to have been taught by his father not to whip livestock, as this results in stress; and the livestock destroy vegetation and soil from running around haphazardly. Additionally, pastoralists in both study sites described limping to be an indication of poor rangeland condition with wet soil or ticks' presence.

Mobility between different vegetation types was described as an indigenous practice by the pastoralists. The semi-arid pastoralists use the Succulent Karoo as a winter grazing area, and the Nama Karoo is used as a summer grazing area. Similarly, pastoralists in the mesic rangelands move their livestock to graze on the soetveld in winter and move to the suurveld during the summer season.

Discussion

The use of palatable plant diversity as an indicator for rangeland condition is common amongst African herders (Samuels et al. 2018). The current study's results of the use of livestock behaviour to monitor rangeland condition, are concurrent with Dabasso et al. (2012).

Transhumance is practiced to exploit seasonal availability of natural resources (Ntombela et al. 2024); and forms part of ethnic identity across global indigenous communities (Blench 2001). The transhumance routes followed indicate a rich understanding of natural resource distribution and availability in the rangeland.

Pastoralists have over many years, accumulated and transferred indigenous knowledge; and it is from this knowledge that decisions are made. Therefore, knowledge and goals need to be integrated into rangeland management for increased and sustainable production. This requires expertise and methodology integration of social sciences into the rangeland profession. Research such as this current one could potentially add to the agricultural education sector of South Africa to highlight the value of agro-ecological knowledge in livestock production and rangeland management, leading to knowledge co-production.

Typology of subjectivities in relation to grass management

Pereira Machin, M; Areosa, P; Carriquiry E; De Hegedus, P

Instituto Plan Agropecuario, Br Artigas 3802, Montevideo, CP 11.700, Uruguay.

Key words: typology of subjectivities; grass management; extension; grasslands.

Abstract

In Uruguay, most cattle and sheep herds graze on natural grasslands. Research indicates that overgrazing is widespread. As part of the Grassland Management (GM) extension project, research is being developed to identify the different ways in which ranchers think about what they understand by GM. This set of different ways is called a typology of subjectivities. From these differences, five ways of thinking about GM emerge.

They are, 1- from the whole (which is associated with rotational grazing and implies considering cattle and sheep herds, soil, pasture and human resources), 2- from the grass, 3- from measurement, 4- from visual observation and 5- from the body condition of cattle herds. Based on similarities, it is possible to generate two macro-groups that facilitate analysis. The proactive rational macro-group (groups the whole, the grass and measurement) and the reactive rational macro-group (groups visual observation and body condition). Each macro-group has its ontological dimension (what to look at?), epistemological dimension (relationship between the rancher and their reality) and methodological dimension (how to look?). The average GM subjectivity profile for all the cases analysed (26 farms) prioritizes the whole or grass view and rejects visual observation (which implies that they prefer to measure).

One of the advances of this project is the identification of methodological views in each macro-group. These views are the gateway for technical assistance and rural extension (TARE). This means that TARE must work orienting their strategies according to each macro group rationality. From which it is deduced that it would not be correct to emphasize measurement and not work with the more traditional producers who focus on the visual observation (as suggested by the traditional theory of rural extension).

Introduction

In Uruguay, most cattle and sheep herds graze on natural grasslands (Pereira Machín, 2011) Research indicates widespread overgrazing (Paruelo et al., 2000). As part of the GM extension project, research is being conducted to identify the different ways in which farmers think about and understand GM. The project, launched in 2021, seeks to improve grassland management by identifying good practices that promote sustainable systems (Fiore et al., 2020). As stated by Freire (1973) it is difficult to change a person if you do not know how that person thinks and how they interpret their reality. By understanding how they think, learning strategies can be properly designed to fit their needs, values, and practices. This study analyses the subjectivities regarding GM of 26 ranchers.

Methods

A qualitative methodology was used, based on structured interviews with 26 ranchers, analysing their perceptions regarding GM. The establishments were chosen in the following way: a public call was made to participate in the project, and those that, according to the technicians' knowledge and/or consultations, were doing interesting things from a pasture management point of view were selected. The interviews included questions about grazing dynamics, livestock management, and emergency response.

Regarding grazing dynamics, the questionnaire questions referred to: what they look at to manage pasture, what stocking rate they use, whether they implement occupations and rest periods, criteria they use to make decisions, whether they know their stocking rate, how they plan grazing, whether they have specialized areas according to species (sheep and cattle), how they conduct field visits to make decisions.

Regarding livestock management: whether they have specialized areas according to species (sheep and cattle), whether they manage fixed lots, whether they supplement or not, whether they use improvements or not, which categories they use them with, etc.

Regarding emergencies: questions were asked about which emergencies they faced, with emphasis on the measures taken during droughts, especially.

The responses were analysed qualitatively, interpreting them to identify emerging themes that allowed for the establishment of differences.

Results

Five types of subjectivities were found regarding GM:

- **Prioritizes the whole:** A systemic vision related to rotational grazing that considers technical and human elements (Cros et al., 2004).

- **Prioritizes the grass:** Prioritizes grassland management as the basis of sustainability, emphasizing that "grass makes grass" (Bove, 2023).

- **Prioritizes measurement:** Uses indicators such as the Food Plate Index (FPI), a simple but robust forage budget, for data-driven decision-making (Duarte et al., 2021).

- **Prioritizes observation:** Based on the visual interpretation of grass and animals through a "trained eye" (Segarra Ciprés and Bou Llosar, 2004).

- **Prioritizes the body condition of the animals:** This is the traditional view that values accumulated experience as the main guide (Morales et al. 2005).

The following are representative statements of each of these types of subjectivity:

"Grass management involves taking into account the system, which includes the grass, the animals, the soil, and the human factor”. (prioritizes the whole)

“The first step is to assess the grass: the grass itself creates more grass”. (prioritizes the grass)

“If you cannot measure, you cannot manage”. (prioritizes the measurement)

“The eye measures by observing and makes good estimations” (prioritizes the observation)

“The first step is to observe the body condition of the cattle." (prioritizes the body condition)

Discussion

The five approaches can be grouped into two broad groups that we call "rational-proactive" and "rational-reactive." We believe this is an appropriate approach due to the conviction that within each macro-group there are similarities, exchange dynamics, and grey areas that make it advisable to work with the broad groups, not with the isolated types. The name respects the original classification of the Instituto Plan Agropecuario (proactive and reactive), emphasizing that both approaches are rational.

This classification highlights the epistemological dimension (the relationship between the producer and "their" reality: proactive or reactive), which is linked to the ontological dimension (what to look at in reality: the grass or the livestock). The novelty is that this research incorporates the associated methodological dimension (how to look: measuring or observing). This dimension is important because it gives value to the fact that there are not only "objective" forms of knowledge through measurement, but also through observation (all rationales). But also, it should be said that it is through these methodological views that TARE services express their intervention strategies.

The "rational-proactive" comprises three related visions: those who look at the whole (practice rotational grazing), those who look at the grassland, and those who measure. The three views focus on the grass with nuances. Those who practice rotational grazing have a global vision (not just plants). Those who focus on grass and those who emphasize measurement share common core values: grass makes grass, and without measurement it is impossible to manage it. It is likely that those who practice rotational grazing also share them. Those who measure use numbers, records, and instruments such as the green folder, the FPI (they are likely to be younger and with more women presence).

The "rational-reactive" macro-group comprises two related views: those who use visual observation and those who look at the body condition of the animal. We could say that both aspects characterize the traditional livestock producer. Those who observe visually prioritize the experience that accustoms the eye to "see well."

Intervention strategies must consider the two major rational logics described above. For the "rational proactive" macro-group, the intervention strategy must work with instruments such as the green folder, or the FPI. The numbers speak for themselves and can be the basis for moving towards scaling proposals. For the "rational reactive" macro-group, the proposals must be adapted to the cultural specificities of the group. The numbers must be accompanied by images that speak for themselves and the systematization of experiences that are illustrative.

In both cases, two considerations apply. First, the rancher workshop/group is an appropriate tool that constitutes the innovative core of a process that then poses the challenge of achieving scalability, what was previously called dissemination. And the challenge arises because much of the learning that occurs at the "workshop/group" level is the result of interactions and experiences that cannot be scaled on their own. Second, technical messages should seek to integrate the productive, economic, and environmental aspects. It can be difficult for the producer to understand them separately, especially the environmental aspects (Vanclay, 2004). The environmental dimension tends to be an integral concern in the rational proactive, while in the rational reactive it refers more to the economic dimension (that the company continues to generate income and work).

Conclusions

The study identifies the existing subjectivities in relation to the way producers manage grass. Recognizing these subjectivities is key to designing effective interventions. The study identifies five different ways of understanding pasture management, which can be grouped into two main types: rational proactive and rational reactive. This characterization respects previous work carried out by the Instituto Plan Agropecuario. The innovative contribution of this research is in two aspects. First, it allows us to better understand the heterogeneity that exists within each typology (the different perspectives). Second, it allows associating a methodological perspective with each typology. This gives the research an applied character. That is, it guides us to specify the intervention strategies in better terms.

By prioritizing the rational character of the two typologies, it follows that the central idea from the TARE services should not be to promote the transition from visual observation to measurement. Rather, we must work with all producers, adapting the materials to cultural specificities when necessary. Traditionally, ATER theory suggests working with the most receptive (in this case, the rational proactive typology) and waiting for natural diffusion (scaling) to occur. Here we propose, to accelerate changes, to work with everyone, which implies recognizing the different subjectivities. We know it is a challenge: it is easy to say but difficult to apply.

Abstract
The Arizona/Utah Range Livestock Workshop & Tour builds cooperation and understanding between public land grazing permittees and federal agency personnel through science-based education. The workshop provides information on livestock production practices and addresses controversial grazing issues in a non-confrontational environment. Topics range from animal handling, vaccination, and health to solar development, partnering with public land agencies, and recreation effects.

Introduction
The Arizona strip is a vast track of land located along the border of the states of Arizona and Utah in the United States. It covers over 3 million acres, and due to its accessibility limitations imposed by the Grand Canyon it is primarily accessed by ranchers in Utah and Nevada. The vast majority of this land is public land and is owned by the citizens of the United States of America, as such it is managed by the Bureau of Land Management (BLM).

Ranchers have been grazing livestock in this area since the 1800s and is currently the source of 100,000 Animal Unit Months (AUMs) of grazing, with an economic value of $7.1 million/year (Heaton, 2024). and is especially important in winter months.

In the mid 1970s grazing on the Arizona Strip became a contentious issue in Southern Utah, Northern Arizona, and Southern Nevada due to the completion of the "Hot Desert" Environmental Impact Statement coupled with the designation of the Desert tortoise as an endangered species. Many allotments were closed and ranches were forced out of business. The AZ/UT Range Workshop was developed by Utah State University Extension and the University of Arizona Cooperative Extension in response to these issues with the goal to bring ranchers and government agencies together to work on these problems and learn how to best manage allotments. The first workshop was held in 1978 and has continued for 46 years as a free workshop with the goals of strengthening relationships and bringing cutting edge science-based knowledge to its participants. This workshop' funding is sponsored by ranchers, local businesses, and conservation districts.

Today, the workshop consists of two days of workshops, presentations, and vendor displays with a third day being spent on a rancher's allotment learning about their range improvements, innovations, and participating in hands on workshop to learn how to manage allotments better.

These workshops are evaluated by University Faculty to determine the effectiveness of each workshop and to help guide the following years workshop topics and tour locations. Continuous evaluation and adaptation ensure that the range livestock workshop remains aligned with the educational needs of grazing permittees and supports effective collaboration between ranchers and public land agencies. Looking ahead, USU Extension will strive to continue this program's long-standing success by delivering science-based education and enhancing relationships between ranchers and government agencies for years to come (Heaton et al. 2024)

Methods

Needs Assessment As mentioned in the introduction the workshop is evaluated each year with the results serving as a needs assessment for the following year. The results of the evaluation are distributed to the planning committee annually to help guide topic selection. Once topics are selected, speakers are then identified and booked for the workshop which takes place annually in March.

Goals and Objectives The goals of the AZ/UT Range workshop are to increase knowledge of participants on the previous selected topics. A pre/post evaluation is given at the end of each workshop to evaluate overall knowledge gain on each topic covered at the workshop. The evaluation also collects data on the demographics of each participant, overall satisfaction of the workshop, venue, vendors, food, and to identify information that participants would like to learn about the following year.

The tour is likewise evaluated with a focus on the stops of the tour and knowledge gained on different topics covered at each stop with a pre/post survey. Information is also collected on participants preference for the following year's tour location and overall topics.

Evaluations and Analysis As previously mentioned, evaluations are distributed at the end of each workshop. The evaluation includes a pre/post survey to determine the percentage of knowledge gain. Short answer questions to determine changes in behavior, and collects information on participants age, occupation and how often they have attended this workshop.

To calculate the percentage knowledge gain for the group, use the following formula was used for absolute percentage change:

$$\text{Absolute Percentage Change} = \frac{\text{Post-Test Score} - \text{Pre-Test Score}}{\text{Pre-Test Score}} \times 100$$

Results

Evaluations from the 2024 Arizona/Utah Range Workshop and tour evaluated 9 presentations with a pre/post survey and found significant knowledge gains in each of the topics covered. The topic with the most substantial growth was "Vence" (Virtual Fencing) which is a topic that had not been covered in prior years. The least impactful topic was "Plant Response to Grazing" (see Fig. 1), which had been covered in prior years and was also demonstrated on the tour in 2024. In addition to the percent of knowledge gain a simple t-test was used to evaluate each topic and found a significant difference in knowledge gained across all topics.

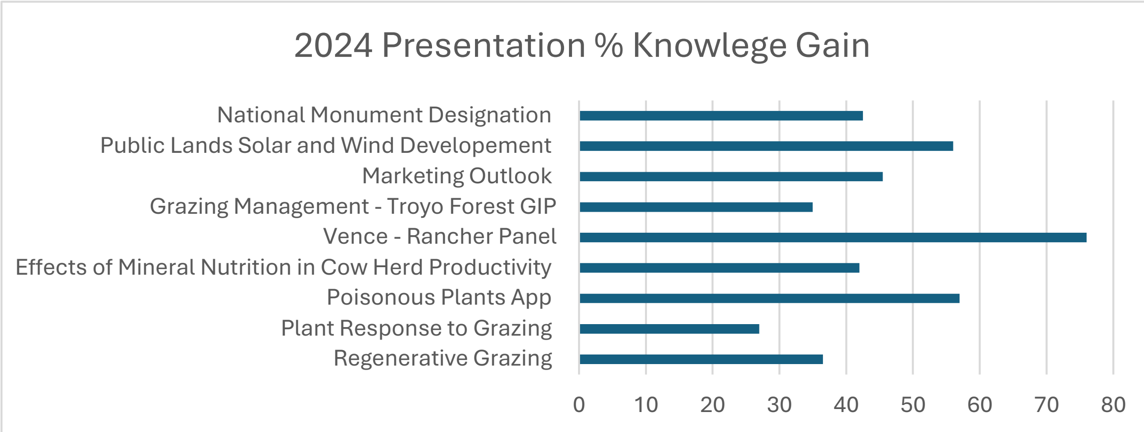

Fig. 1. Graph showing % knowledge gain by presentation topic.

Demographics and Behavioral Change:

Evaluations of the Arizona/Utah Range Workshop and Tour for the past 20 years have identified changing trends as well as reenforced old ones. Attendance has stabilized around 255 participants/year, but the age demographic has changed significantly over the past 20 years. (see Fi 2.). In 2003 we found that 64% of our participants were over the age of 50 with 34% being under the age of 50. Recent evaluations found that 68% of participants are under the age of 50. In fact the largest demographic in 2024 was in the age range of 20-29 years old, making up 40% of all participants. Participants perception on different topics also show a favorable change of at least 69% of participants indicating that they will change their behavior as a result of what was learned at this workshop. (See Table 1.).

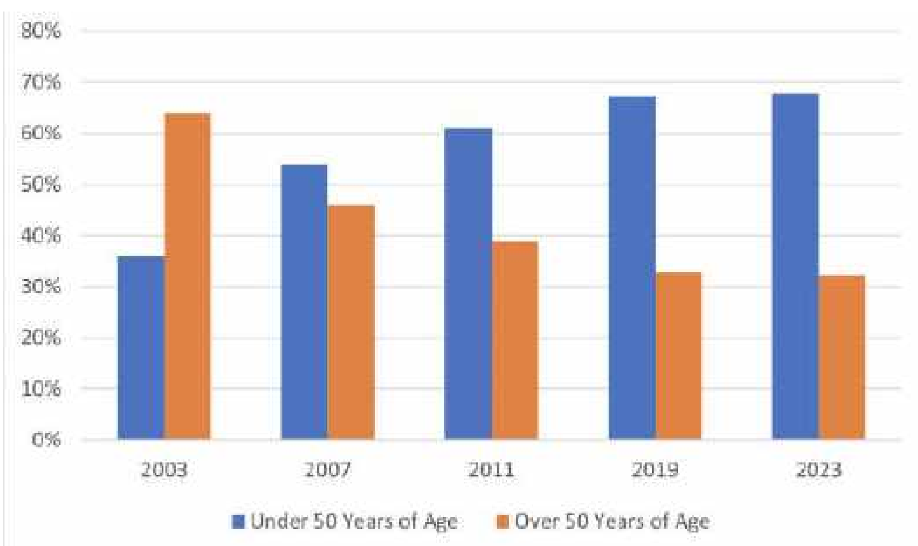

Fig 2. Age Demographics 2003-2023

I am likely to use some aspects of this activity As a resource I will make available to producers	69	10	21
I am likely to use some aspects of this activity As a professional development tool for my peers	69	9	22

Discussion

The Arizona/Utah Range Workshop and Tour has demonstrated positive overall findings in knowledge gain to its participants across multiple topic areas consistently for its 46 years of operation. The workshop provides participants with opportunities to expand their knowledge, skills, and relationships with other stake holders in range management.

The workshops evaluations capture knowledge gains and behavioral changes adequately but reveal the need for adaptations to better capture impacts of the workshops additional goal of building relationships between government land management organizations and ranchers. Some publications on this workshop have been published through Utah State University Extension with additional research needing to be done on long term impacts from this workshop on ranching operations on the Arizona Strip.

To build on the 46 years of success that this workshop has demonstrated, organizers will need to continue to focus on the needs of participants by continuing to focus on new technologies, practices, and marketing opportunities that participants require to stay relevant in today's industry. With a large shift in population age demographics this workshop is uniquely positioned to have a large impact on the new generation of ranchers in the southwestern United States. In conclusion this workshop has been very impactful in providing science-based information on a wide variety of topics and additionally has served as a blueprint to other similar workshops across the western United States. It is well known for its ability to bring land managers together and solve problems.

Abstract

Utah State University (USU) Extension provides outreach and technical assistance to urban and small acreage producers to help operations navigate local environmental and urbanization challenges. According to the 2020 U.S. Census, Utah was the fastest-growing U.S. state from 2010 to 2020. Most urban development is concentrated along Utah's I-15 corridor, known as the Wasatch Front, which is sandwiched between major mountain ranges. Salt Lake County is Utah's most densely populated county, and in 2020, it housed 36% of Utah's total population (U.S. Census Bureau 2020). Land acquisition is a significant concern for local producers due to high land costs and population density (≈ 1,600 people/square mile). The USDA Census (NASS 2017) reported that most farms (66%) were between 1 and 9 acres and therefore most producers in Salt Lake County farm or graze small acreages that interface residential communities. Salt Lake County has an arid climate and low annual participation rate (34 cm) so supplemental irrigation is essential to sustain many landscape plants (Kopp et al. 2013).

Rapid urbanization has strengthened local interest in the preservation of remaining farms and grazing lands. For example, Salt Lake County government developed an urban farming initiative that explores opportunities to lease County-owned land parcels to local agriculture operators. In 2023, a private landowner/leaser contacted USU Extension seeking assistance to enhance the environmental function of the property. The 5,000 square meter parcel could legally house up to 6 horses and was surrounded by adjacent wetlands that ultimately drained into an area watershed. Extension worked with the client to develop an urban interface plan, design a rotational grazing pasture system, and address soil management and water quality concerns. Key takeaways from this case study illustrate ways Extension can work with small acreage operators in urbanized areas to enhance sustainable management and environmental stewardship of fragmented agricultural landscapes.

Introduction

The Cooperative Extension Service in the U.S. provides research-based, non-biased information and outreach to residents. Traditionally land grant Universities specialized in mechanical arts and the agricultural sciences and are still vanguard providers of technical support to local producers and land managers. Statewide, Utah has lost about 20% of its agriculture lands (2.7 million acres) in the past 60 years to development and mining extraction which has impacted food security, clean water, wildlife habitat, and recreational opportunities (Jeremias 2024). Nearly all farms and ranches in urbanized Salt Lake County have been converted to homes and businesses and many remaining agriculture properties are fragmented and surrounded by public and private development. Animal managers in urban areas, particularly those with surface water bodies, face an elevated risk of the public coming into contact with contaminates such as pathogens and nutrients that originated from their operation. A 2023 outbreak of Shiga toxin producing *Escherichia coli* O157:H7 in Utah sickened at least 13 children who were thought to be exposed via untreated irrigation water. City dwellers are not always attuned to the dangers of untreated water bodies. In the Utah case, the sickened children were drinking and playing in contaminated water thought to have originated from animal feces in open reservoirs. A subsequent Center for Disease Control (CDC) incident report cited a need to better educate the public on the dangers of human and animal exposure to contaminates in untreated water. Each year the Utah Department of Environmental Quality monitors several water bodies within Salt Lake County for waterborne pathogens and Harmful Algal Blooms (HABs). Cyanobacteria are aquatic bacteria that photosynthesize like algae and form blooms in surface water bodies with high nutrient loads, often from sources such as manure run-off and landscape fertilization that reaches storm drains. Therefore, waterborne pathogens and HAB blooms directly connect property management decisions with public health and safety concerns in urban areas. HAB warnings are frequent in Utah in the summer months and impact residents who visit public parks and open spaces with access to reservoirs, streams, and open canals carrying water. Posted warnings inform visitors that HABs produce dangerous toxins and pose a serious health risk to humans, pets, livestock, and wildlife exposed to the water. From personal experience, many in the public are poorly informed on the exposure risks of waterborne pathogens and HABs. Our Extension office fields several calls each year from the public with questions about potential health implications to both people and pets. Therefore, the objectives of this case study are to detail a site management plan that was developed with one urban horse manager on best management practices that both enhanced the property site and minimized the risk of nutrients and pathogens contaminating water sources. Discussion from this case study carries relevance to city managers that must conscientiously navigate decisions pertaining to the co-existence of urban agriculture operations and adjacent communities.

Methods

Three site visits were made to a 5,000 m^2 horse farm in 2024. The property was assessed for size, proximity and orientation to adjacent properties and uses, slopes and other geographical features, water bodies, pasture condition, manure management, barn and corral lay-out, irrigation infrastructure, soil conditions, and existing flora and fauna. Approximately a third of the farm site housed the barn, parking area, and corral and was owned by the operator. The remaining property (pasture) was leased from the County. Another property immediately adjacent to the farm site was also housed horses and was leased from the County. The leased parcels were connected to and part of the Holladay Lions portion (153,000 m^2) of Big Cottonwood Regional Park which is owned and operated by Salt Lake County Parks and Recreation. The broader public park features natural areas, wetland drainage areas, playgrounds, sports fields, and a recreation center. Site assessment observations for the study area are organized under the subsequent pasture, manure, and landscape headings.

Pasture

At the time of site visits, there was very little vegetative growth on the leased pasture area. A major priority of the property manager was to increase vegetative growth in the pasture in an effort to restore seasonal grazing potential. The adjacent corral and barn were zoned to house up to 4 horses, and the leased property was zoned for 6 horses. The operator wanted to utilize the 3156 m^2 pasture for forage. A small seasonal stream bordered the pasture area on two sides. During the first site visit in May 2024, the stream contained water and flowed toward wetland drainage areas. The stream delineated the property boundary between two leased parcels, so the manager had fenced along the stream to keep the horses out of the waterway and restrict their movement off property. Natural vegetative growth on the streambank was lush and diverse with desirable species, such as timothy (*Phleum pratense*) in abundance. The natural existence of timothy and other wet thriving plant species indicated adequate soil moisture. The manager did have access to treated water via the corral, however the pasture did not have permanent irrigation infrastructure at the time of site visits.

Manure

Environmental Protection Agency (EPA) and state animal feeding operation (AFO) regulations prohibit any discharge of manure or feed into a federal water or water of the state (USU 2024). There is no minimum amount of contamination, or number of animals exemption. There is a grazing exemption where livestock within the pasture can directly access water but only if there is adequate vegetation present across the entire area. Horses produce about 5.4 metric tons of manure per year, and that amount doubles with bedding included. Therefore, six horses housed on a 5,000 square meter parcel will generate 65.3 metric tons of waste per year. During site visits, the manager was disposing all waste via sanitation collection. Although discarding manure into a landfill is not ideal from a nutrient recycling perspective, it is a safe disposal method. The site was assessed for feasibility of on-site composting because many local gardeners seek out sources of nutrients like composted animal manures. Manure storage ordinances vary by state and municipality, but a pile must typically be distanced a minimum of 30.48 meters away from streams, ponds, or wells. Nutrient values vary from source and type, but horse manure contains roughly 0.7% N, 0.4% P_2O_5, and 1.1% K_2O (Stock and Miller 2019). Manure that enters water sources via run-off or windblown dust can contribute to nutrient loading in surface water bodies causing algal blooms and other environmental degradative processes.

Landscape

The land manger prioritized landscape improvements including dead plant matter removal, noxious weed control, planting of desirable trees, shrubs, forbs, and grasses, and diversification of landscape plants. Trees and shrubs are important assets to pastures since they help cool the landscape in the summer and provide a windbreak in cold weather. Root systems stabilize streambanks and hillsides, reduce run-off, and operate as landscape filters that trap materials and settle sediments. Diverse landscape plantings also enhance habitat for beneficial insects and urban wildlife. Dense vegetation keeps the soil covered and helps trap and reduce dust. Our Extension team worked with the land manager to identify desired vegetation, identify and manage noxious weeds including appropriate herbicide options for use around water bodies, discuss long-term control of invasive trees and shrubs, and draw connections between soil conditions and appropriate plant selections.

Results

Pasture

Given the limited size, proximity to wetland soils, and testimony from the manager that the pasture stayed green most of the year, it was determined that established pasture grasses would likely receive adequate moisture most weeks through subsurface irrigation. The manager was encouraged to manually run a sprinkler during grass seed germination and prolonged periods of dry conditions. Soil samples collected from the pasture area indicated a loamy soil with normal pH (8), very high salinity (3-5 dS/m) and high to very high phosphorus and potassium levels (mg/kg). Samples within the pasture area were difficult to collect due to extreme soil compaction, so the manager was advised to till the soil prior to seeding to lessen surface compaction. There is a correlation between blade height and root depth, so the manager was instructed to restrict grazing until the pasture was 17.8 to 20.3 cm in height. Grazing below 7.6 cm drastically impacts root mass which weakens the grass stand and pre-disposes the pasture to weed invasion (Barnhill and McKendrick 2008). The manager was encouraged to divide the pasture acreage into two to three paddocks and develop a rotational grazing plan which confines animals in one section of paddock while non-grazed areas 'rest' and produce forage. In Utah, most irrigated paddocks can be re-grazed after three to four weeks of 'rest' and a minimum of four paddocks are necessary for sustainable rotational grazing systems. The leased pasture footprint was insufficient for four confined paddocks, so the manager was encouraged to utilize the corral when pastures needed rest and to feed hay. One suggestion was to allow horses paddock access for a few hours in the morning and evening to ensure the nutritional needs of animals were met while eliminating excessive trampling. It was also advised to only irrigate after grazing to avoid hoof compaction on wet soils.

Manure

Water test results from two on-property sample points and one additional sample point on public park property identified water highly contaminated with coliform with much of the contamination being from *E. coli*. *E. coli* levels from the two on-property samples both tested >2,400 Org/100mL and a sample taken on public park property tested 550 Org/100mL. Although not all *E. coli* bacteria make people sick, the test results do indicate that fecal material was entering water sources. Adjacent parcels of land leased by other managers also allowed for equestrian use, so the precise source/s of contamination was unclear. Drinking water should have <1 colony/100mL of water, and no *E. coli* present. Recreational water, streams or lakes are considered safe if *E coli* is <235 Most Probable Number (MPN)/100mL in any one sample, and an average <126 MPN/100mL from 5 samples during a 30-day period (UDWQ 2021). Based on water and soil test results, manure spreading on pasture was not advised. Soil test results indicated very high phosphorus levels which raised concerns of excessive nutrient loading in nearby water sources. On-site composting and/or exposed manure storage was also not advised because it would be difficult to locate a pile 30.48 meters away from a water body and a third of the property was severely sloped. The operator could consider a fully contained manure storage system where run-off is prevented and manure could be collected by local gardeners instead of being transported to the landfill. The manager was advised to divert any clean water (i.e., rain, snowmelt) run-off away from the corral and consider establishing vegetated peripheral berms around the paddocks to prevent run-off from the pasture perimeter. Increased vegetative growth in the pasture would increase water infiltration rates, reduce run-off, improve nutrient and water holding capacities, alleviate soil compaction, and induce soil structure formation and hence should be prioritized in short and long-term site improvement activities.

Landscape

During the first site visit, the land manager shared efforts to vegetate streambanks with native plants. The manager was advised to leave the streambank vegetation undisturbed and consider planting seeds to minimize digging. Berm plantings around pasture perimeter should include plant choices that are not hazardous or harmful to the horses and provide the animals an escape from the elements. Due to the elevated salinity levels in the pasture soil samples, the manager was advised to select plants tolerant of elevated salts. Many Utah native riparian plants have moderate to low tolerance of high salinity and/or compaction, so it is best to select plants with higher tolerances to existing site conditions. Other areas of the property were more favorable for heat and drought tolerant plant selections. The land manager was informed that drought tolerant trees and shrubs should receive frequent irrigation prior to establishment. Our advice was to spread the timing of the new plantings out so she could keep up with the irrigation needed to establish new landscape plants. Our team advised that areas identified for invasive species removal should also be targeted for new plantings to ensure disturbed ground was filled by desirable species. Finally, we encouraged the land manager to take advantage of appropriate plants that are readily available and easy to plant, such as willow whips, which are easy to harvest and root. Qualitatively, the manager shared that she has seen greater abundance in flora and fauna (birds, insects, native species) since initiating efforts to improve and diversify landscape plantings.

Discussion

Findings from this case study illustrate a need for livestock and grazing educators to work with livestock operators in urban interfaced areas. Since conducting site visits, our Extension team learned that Salt Lake County Parks and Recreation is looking to phase out lease opportunities for equestrian use on park land. An updated Master Plan projects efforts to revegetate and enhance natural areas in park land currently leased for equestrian use. Multiple horse operators with short term County leases have expressed interest in our findings, as they present a case to park officials that horses can be housed on park property in an environmentally sustainable way that also protects health and safety. Recent discussions with the Utah Division of Water Quality and Department of Agriculture and Food officials have highlighted the role of urban livestock and water degradation. More education and oversight are needed to help protect water sources in densely populated areas. Case studies that evaluate site details and constraints and provide appropriate recommendations offer a perceivable conversation bridge between user groups and officials which can both improve management practices and preserve the existence of livestock management operations embedded in urbanized landscapes.

Key words: co-production; participatory research; range sheep systems; social-ecological ecosystems; transhumance

Abstract
Rangeland social-ecological ecosystems experience conflicting social goals for land use that can stall progress towards effective governance and land management. This can be detrimental to social and ecological wellbeing. In the western United States, disparate land use goals for wildlife conservation and ranching within sustainable rural communities have led to polarized management contexts and legal challenges. At the US Sheep Experiment Station (USSES), a federal research ranch located in the Greater Yellowstone Ecosystem (GYE), researchers, diverse community partners and organizations, and ranchers are asking: what would happen if conflicting groups agreed to manage the land together in a participatory, co-production manner within a scientific research project framework? Could we learn to work with, rather than control, the rangeland social-ecological system and one another to achieve common objectives and outcomes? In this study, we report on the initial phases of the USSES Collaboratory, a multi-year collaborative adaptive rangeland management project focused on rangeland domestic sheep systems, rural livelihoods, biodiversity conservation, and climate adaptation. Initial social and ecological assessments have been used to inform the development of management goals and experimental treatments for a participatory grazing experiment. We report early key lessons from the baseline social assessment and initial objectives-setting workshops, which will inform how we work to bring divergent viewpoints together to build common ground based on increased trust and a new, shared understanding of complex systems dynamics.

Introduction

Rangeland social-ecological systems include multiple ecological processes and societal goals including livestock production, biodiversity conservation, and recreation, and management for numerous ecosystem services (Reid et al., 2014). The potential for conflict over uses of these systems is particularly high for privately-owned working lands where ranchers or pastoralists operate within a patchwork of public-private land ownership near protected areas (Bindi, 2022). Local-scale conflicts over management and policy can become regional, national, or even international discourses (Epstein et al., 2021; West, 1994). Diverse and competing demands of rangelands' social-ecological systems highlight larger social issues related to incongruent values and goals for local food systems and conservation (Barry & Huntsinger, 2021; Loconto et al., 2020). If left unaddressed, disagreements over land use values lead to continued frustrations and actions that drive negative social and ecological outcomes (Webel & Galtung, 2007).

These conflicts are evident in the Greater Yellowstone Ecosystem (GYE), the broader ecological region that surrounds Yellowstone and Grand Teton National Parks, federally-protected areas in the US Intermountain West. Here, rangeland-based livestock production shares a diverse and complex landscape with numerous protected species across a patchwork of public and private land ownership patterns. Various actors, including state and federal public agencies, conservation organizations, ranching organizations, and others have experienced substantial conflicts over priorities for land use in this region (Epstein et al., 2021). However, in the ever-changing western US, exurban development and increasing climate variability have induced shifts in ecological dynamics which are threatening the goals of multiple actors at once, including those who have long been foes. As conservation organizations, public land management agencies, ranchers and the ranching industry, and researchers increasingly recognize the value of working together, new opportunities are emerging to transform long-standing environmental conflicts. Transdisciplinary research, which actively engages the knowledge of diverse societal partners and scholars to address society's most challenging problems, offers a methodology by which researchers can initiate new conversations to bridge the social divisions (Reid et al., 2021).

Methods

This paper reports early results from "The Rangeland Collaboratory", a transdisciplinary rangeland research project designed to address adaptive capacity and conflict in rangeland domestic sheep systems in the US Intermountain West. Initial results include: 1) an overview of a baseline social context assessment, and 2) management objectives and hypothesized synergies/trade-offs developed from participant workshops in 2024. The project is based at the US Sheep Experiment Station (USSES), a commercial scale (19,400 ha) research sheep ranch operated by the United States Department of Agriculture - Agricultural Research Service, Range Sheep Production Efficiency Unit (USDA-ARS-RSPER). The USSES is on the eastern edge of the GYE and is comprised of sagebrush steppe and montane/sub-alpine rangeland systems in Clark County, Idaho and Beaverhead County, Montana, USA.

Collaborative adaptive management (CAM). CAM is a form of adaptive management that uses the action-oriented methodologies of participatory research to braid the knowledges of multiple land management and scientific communities with experimentation resulting in the promotion of learning over time (Wilmer et al., 2018). Researchers and partners identify goals, objectives, experimental treatments, indicators for success, and triggers for action. As a management plan unfolds, the science-stakeholder team monitors and evaluates results and options for adaptation and modifies the management plan based on their own learning. Additional levels of learning may be achieved as the team recognizes limitations of their earlier assumptions and modifies actions, objectives, or even the project goal in a co-produced iterative process.

Structure of the Collaboratory. The project is modelled after the Collaborative Adaptive Rangeland Management experiment implemented at ARS's Rangeland Systems and Resources Research Unit in Colorado, USA, but includes several modifications for the USSES context (Augustine et al., 2024). Throughout 2023-2024, social scientists at USSES conducted a baseline assessment of stakeholders involved in ranching, conservation, public administration, recreation, or research in the surrounding region. This assessment involved semi-structured interviews, participant observation, literature review, and initial meetings with various individuals or groups to elucidate key perspectives of public actors (Wilmer et al., 2018). At the same time, the research team conducted plant community and animal science assessments at USSES. Then, we developed an experimental design outlining key parameters (e.g. management of a band of white-face range sheep, no additional fencing), the requirement for certain areas of focus (livestock, social, wildlife, and vegetation outcomes), and identification of which management decisions stakeholders could use in adaptive management (livestock and vegetation management, social activities, etc.). We held a group tour and subsequent meetings throughout 2024 to identify core objectives for a forthcoming adaptive management plan.

Results

Social baseline data reveal context of conflict and collaboration. The GYE has fostered complex forms of conflict among environmental and agricultural interests over priorities for land use, livestock grazing, and wildlife habitat, particularly on public lands viewed as having particularly high conservation value. For example, wildlife advocates and agencies have long worked where livestock and wildlife goals overlap to maintain habitat for some of the continent's most iconic species, such as grey wolf (*Canis lupus)*, grizzly bear (*Ursus arctos horribilis),* Greater sage grouse (*Centrocerus urophasianus*) and big horn sheep (*Ovis canadensis)* whose populations have been substantially reduced due to agricultural expansion and settlement of the region. Conservation advocates we interviewed describe themselves as working to protect and help wildlife, ecosystems, and public access to natural resources. They advocate for increased legal protections and programs to enhance wildlife populations and mobilized litigation efforts to this end. They also take on public education roles and organized support for land management changes, such as reductions in public grazing permits. The ranching industry has sought to maintain the financial and ecological viability of individual ranching operations, and the vitality of rural communities dependent on ranching. Ranchers we interviewed described themselves as stewards of the land. They seek to maintain their ranching lifestyles, cultures, and businesses, and their access to transhumant grazing practices on federal lands. Pressures from a globalized market, increased environmental regulation, and the interactive effects of social and climatic change have prompted them to adapt genetics, range management, and marketing to new realities, and to engage in more collaborative and advocacy activities.

Despite these dynamics, many forms of collaboration have supported solutions for wildlife and land management issues. By the early 2000s, some conservation and ranching advocates across the western US grew tired of persistent conflict and came together to conceptualize "The Radical Center" (White, 2008). This idea recognizes the common need to steward healthy ecological and social systems, and to prevent exurban development (Brunson & Huntsinger, 2008). It motivated a conversation about how enhanced financial and social viability of ranching operations and communities could help limit exurban development and therefore help conserve wildlife habitat.

Table 1: Stakeholder-developed rangeland management objectives (blue cells), and the hypothesized relationships among them, including potential synergies (green cells) and trade-offs (grey cells) for a ranch-scale grazing study in the Greater Yellowstone Ecosystem case study.

	Social systems	Livestock systems	Wildlife biodiversity	Vegetation biodiversity
Social systems	**Multiple uses multiple perspectives; reduce conflict; promote healthy local food systems; increase community adaptive capacity; intergenerational learning**	Increased adaptive capacity, fair wages and profit; reduced conflict; connectivity to local food systems	Increased awareness and connectivity to ecological systems and wildlife; reduced conflict; increased multi-party buy in for science-based management	Increased awareness and capacity to manage for vegetation biodiversity
Livestock systems	Reduced access for livestock to seasonal grazing ranges; increased competition for land use from recreation or development; loss of social license to operate	**Improve animal performance and ranch profitability**	Decreased disease, depredation, or habitat competition; improved trust, reduced conflict in management of livestock-wildlife interactions	Livestock grazing and/or prescribed fire management used to enhance heterogeneity, which bolsters livestock system flexibility
Wildlife biodiversity	Increased negative interactions among public users and wildlife; increased conflict over conservation efforts	Increase disease, depredation, or habitat competition among livestock and wildlife	**Maintain and improve connectivity, biodiversity; reduce conflict with humans**	Increase biodiversity, connectivity, and heterogeneity to enhance wildlife and plant community outcomes
Vegetation biodiversity	Negative effects of multiple land uses, including recreation, urban development or other uses on plant communities.	Negative livestock grazing impacts on riparian or upland biodiversity; loss of biodiversity due to invasion in turn reduces livestock performance	Habitat modification via development, invasive plants, or fragmentation reduce processes that support landscape and regional-scale conservation outcomes	**Maintain or increase habitat heterogeneity and connectivity, and core native rangeland plant communities; reduce invasion**

Identifying objectives for the USSES Collaboratory. In addition to the social baseline assessment, we also engaged participants in the initial USSES Collaboratory meetings to identify which social and ecological objectives they want to prioritize for the participatory grazing experiment. The scientist team provided guidance that objectives needed to include social and livestock systems, as well as wildlife and plant biodiversity realms. Participants outlined key desired future conditions and discussed potential trade-offs and synergies among objectives, which the science team expanded (see Table 1). During objectives workshops, participants discussed the challenge of successfully balancing multiple objectives. They also identified common themes in supporting healthy ecological and social communities, learning, reducing conflict, and coming together on the land.

Conclusions/Implications

We have outlined methodology for the USSES Rangeland Collaboratory, a co-produced research project seeking to find common ground on rangeland systems in the GYE. The baseline social context assessment provides a grounded view of cultural and political dynamics within the GYE, and it will inform more meaningful engagement and learning for participants in the future. Next steps include the development of culturally-oriented activities within the larger project to foster outcomes towards social objectives. We will also co-develop key indicators, treatments, and monitoring plans to advance adaptive management for project objectives over the next two growing seasons via a participatory ranch-scale grazing study. Collaboration with wildlife experts and engagement with agricultural economists will be key to identifying systems level outcomes and synergies/trade-offs among objectives.

Some twenty years after 'The Radical Center' was conceptualized, the GYE face new challenges as climate, land use, and community change dynamics continue reshaping the conversation (Martin, 2019). The USSES Collaboratory follows a CAM model which lends the power of research to help rangeland stakeholders bridge social worlds. Our initial experiences suggest that the complexity of the project creates the need for investment in problem exploration. It is not reasonable to expect research data to sufficiently bridge divergent goals among rangeland actors. The challenge of finding common ground now requires a concerted effort to transform conflict via depolarization, systems-thinking, and science-based solutions that together create a shared, creative search for a new, peaceful reality (Webel and Galtung, 2007; Zecher, 2024). Across the GYE, CAM may require intentional infusion of social sciences and the humanities, including peace studies, which have been valuable in other rangeland systems for challenging assumptions about human-nature relationships and pointing toward productive conflict transformation (Butler & Gates, 2012). Our early workshops indicate the potential of Collaboratory participants to engage in respectful dialogue and problem exploration, but the challenge ahead will be to co-develop creative strategies that actually move the community beyond the livestock-wildlife divide at the USSES and across the GYE.

Key words: long-term; monitoring; value; custodianship; legacy.

Abstract

Long-term vegetation observations are rare but essential for the effective management of our natural assets. Studies of 3-4 years allow us to discern short-term variability, but long-term trends are only detectable over multiple decades. Through a meta-analysis of several medium to long-term studies in Australia—Kidman Springs, 30 and 50 years; Koonamore, 90+ years; the Brigalow Catchment study, 60 years; the Wambiana grazing trial, 26 years; several Australian Wildlife Conservancy sites across northern Australia, 19+ years; and one site in the USA, Jornada, 105 years—we discuss their benefits, the challenges, the management of the resulting data and information, and their future. We will argue that such sites are vital for the determination of the effects of perturbations caused by fire, thinning, grazing, water diversion, soil erosion, pollution, pathogens, weeds, insect pests and feral animals. They provide points of validation for a variety of types of models, help us better understand the systems involved, and inform management. Quite often these benefits are unpredictable and depend on multi-disciplinary synthesis. The interpretation of the data from such sites can be enhanced by integration with longer term remote sensed data. Ongoing measurement, management and custodianship is, however, often fraught. Measurements that were designed, for example, in 1920, are not always seen as relevant today, a disincentive for participating researchers. Support from the institutions managing the sites has proved variable. Sites can be attractive for a sponsoring body for their sheer age, but usually there is little understanding of the discipline involved, or what is required for their continuation. The expectation for data and information from such sites has changed profoundly with time. Repositories and observatories like the Environmental Data Initiative in the USA and TERN in Australia provide data from several long-term sites. We can expect changes and expectations to evolve into the future.

Introduction

Long-term vegetation observations (>30 years) and their derived trends are essential for the effective management of our natural assets. Studies of 3-4 years are able to discern short-term variability, but long-term trends are only detectable over longer time periods (Peters et al. 2014). This is particularly the case with systems that have slow dynamics, such as tussock grassland and forest ecosystem, or soil carbon pools. Rangeland species such as Brigalow have recently been aged at an average of 150 years. Controlled field observations can greatly contribute to the determination of the short to long-term effects of perturbations caused by fire, thinning, grazing, water diversion, soil erosion, pollution, pathogens, weeds, insect pests and feral animals. Müller et al. (2010) listed six main objectives of long-term research, which are the understanding of: (i) large-scale variabilities, (ii) interactions of short-term and long-term fluctuations, (iii) self-organisation, (iv) rare events and disturbances, (v) impacts of anthropogenic use of landscape resources on ecosystem functions, and (vi) generation of knowledge and data for the development and evaluation of ecosystem models. The challenges for long-term research have been found to include sustaining funding, partnership development, maintaining continuity in objectives, and linking scientists and data through communication and cooperation (Gosz et al. 2010).

The enclosures, catchments, management areas, and plots (referred to henceforth as 'sites') reviewed here meet the definition of research infrastructures: a set area or suite of areas within which land management manipulations and experiments (such as variations in fire frequency or the application of different rates of fertiliser) can take place over the long-term. The type of commitment to manage and measure such sites over time extends beyond normal political and funding agency time frames. Australia's National Collaborative Infrastructure Strategy (NCRIS) was established to support facilities that fall outside research grant time frames or outside funding criteria (Phillips, 2018). The Terrestrial Ecosystem Research Network (TERN), an NCRIS infrastructure, for example, has established 'surveillance' plots across the country to provide calibration sites for the assessment of vegetation coverage (Guerin et al. 2020). It will be many years, however, before these plots reach the longevity of the sites being examined in this paper. Existing long-term sites can provide insight into future challenges that may face TERN and similar Global Ecosystem Research Infrastructures as well as continuing to provide useful benchmarks.

Based on a desktop study of five long-term research sites in Australia and the USA, and two medium-term sites, we examine their value, the challenges, and their data legacy. We offer a prognosis for the future for them and other such sites. With the exception of one relatively new suite of sites, they are survivors of their kind, at least in Australia.

Methods

The long-term sites include two studies at Kidman Springs (30 and 50 years), the TGB Osborn Reserve (Koonamore) enclosure (90+ years), the Brigalow Catchment Study (60 years) all in Australia, and the Jornada site in the USA, 105 years (Specht et al. 2024). The shorter-duration sites include monitoring of adaptive fire management at multiple locations in northern Australia by the Australian Wildlife Conservancy (AWC, ~20 years), and the Wambiana grazing trial (26 years). We documented the original purpose for the sites, the value that had been gained over their lifetime, their recorded legacy, and the challenges that had been faced. Using this process we were able to highlight commonalities across sites, the opportunities presented by their existence, and reflected on the management options for their continued survival and how the data and information gathered at each site is handled.

Results
Management of these sites, with the exception of the AWC sites, is confined to public authorities, such as government departments, universities and federal research agencies, usually in combination. For example, Kidman Springs is run by the Northern Territory (NT) government with CSIRO staff, a federal research agency, contributing to measurements, while the NT Department of Agriculture and Fisheries has run the fire experiment. The Jornada long-term Ecological Research (LTER) site is also supported by multiple programs and institutions, notably the US Department of Agriculture (USDA) and New Mexico State University (NMSU). AWC, a not-for-profit organisation, runs its sites in collaboration with landholders, including Indigenous groups and the AWC itself (Fitzsimons 2015). The TGB Osborn Reserve, however, has been singularly managed since its establishment by the University of Adelaide (UofA). Most sites have attracted funding for research work or training at various occasions along their life span which has helped their sustainability through contributions to management and the ability to demonstrate value.

The utility or value of the study sites ranged from providing points of validation for landscape-scale models of pasture yield (Jornada: Hartman et al. 2020; Robinson et al. 2018), the effects of climatic or land-use change (Jornada: Christensen et al. 2023), hydrological and soil change due to land clearing, land use and management change (Brigalow: Thornton and Elledge, 2022), the detection and attribution of changes due to CO_2 (Brigalow: Orton et al. 2023), to the economic and ecological benefits of managing for climate variability (Wambiana: Neilley et al. 2018). Through these sites, the impacts of different fire regimes and whether they are achieving management goals has been assessed (Kidman Springs: Cowley et al. 2014; AWC: Legge et al. 2011). Observations reaching beyond the lifetime of an average research project has allowed the development of relationships and hence understanding of the systems involved. Quite often these benefits have been serendipitous and unforeseen. The sites are valued by their respective researchers for their curiosity value as they return for the next measurement. By enabling evidence-based decision making they provide economic benefit for important economic activities like livestock production; they also mediate/reduce the impact on biodiversity and downstream ecosystems like the Great Barrier Reef. To study sponsors, such as government, it is likely that the value is demonstrated at a higher level, such as the inclusion of findings in government policy, in response to a Senate Inquiry, or when used in a court of law. These measures are unlikely to be of equal appeal to every audience, and hence will provide varied and perhaps limited justification for continuing a study.

All sites have faced challenges to their existence. The longer-term sites have all experienced uncertainty of funding and continuing agency support. Maintaining the original objectives especially over a long time is always problematic: standards, staff and technology all change and the understanding of the purpose and sense of responsibility for each site wavers. The duration of the Jornada site is remarkable for the continued support (albeit with breaks) of the USDA and NMSU, augmented by membership of the LTER. Koonamore has enjoyed continuous support from the UofA, but has recently turned to crowd-funding for basic maintenance. It was used for regular teaching for many years, but the advent of remote learning and the distance from the university campus (400 km) has limited this to annual measuring trips by volunteers. AWC is committed to testing the effect of interventions and management practices which assist in maintaining the ecological health of their sites.

The expectations of data availability from such sites has changed profoundly with time, from paper records, journal articles and theses, through to the open data delivery we see today (FAIR; Wilkinson et al. 2016). Repositories and observatories like the Environmental Data Initiative in the USA and TERN in Australia provide data from several long-term sites and the management of these sites has had to adapt to meet the new conditions and expectations of open science. We can expect the same changes and expectations to evolve further into the future.

Discussion

Our analysis shows that the data from these sites are valuable in many ways. On-ground observations provide the point of truth for satellite imagery and record floristic changes not provided by the satellite record. Multidecadal monitoring of single treatments or land use in a discrete area provides a unique opportunity to document responses to climate change, having removed externalities that confound these observations in mixed use and management systems. Custodianship of the sites and observations over time is difficult to maintain, however. The attraction of being involved in scientific measurements of such sites dwindles with time as building on the shoulders of others is not an easily marketable quantity for academic promotion. Unless there is a fixed and well-invested bequest, the cost of running long-term sites becomes challenged by other, more state-of-the-art, investments, such as flux towers, square mile radio telescope arrays, and Free-Air CO_2 Enrichment (FACE) experiments. The (managers of) long-term sites could be well-advised to incorporate such facilities in their sites to retain currency.

It appears that to survive, these sites need to be multi-purpose, maintain a clear sense of value for all concerned, encourage and acknowledge collaboration, and ensure there are rewards for involvement (see Alber et al. 2021). Protecting the sites by membership of a network might prove advantageous (viewing the strength of the LTER network around the world as an example) as would linking with major observatories and data repositories such as TERN. The data collection at long-term sites is often different from the standardised data collected by such observatories so strategic links will need to be made, but such a move will help ensure the legacy of these sites is secure. Making the data easily discoverable and providing regular analyses for a range of societal actors and national accounts will illustrate the value of the sites.

It is clear that these sites require active champions, ensuring a flow of quality results and endorsements of their value. A program of marketing to relevant stakeholders and potential funders is required and this would be best managed by sharing within a network of similar sites. Creating a catalogue of similar sites (mid- to long-term), and stratified according to type and use, would be a good first start in creating such a network.

Acknowledgements

We acknowledge the custodians, sponsors, users and supporters of these sites over the many years.

Key words: grazing; pasture; longitudinal; frequency; comparative analysis

Abstract

This paper outlines the review and development of site selection and field data collection protocols for enabling the continuation of the state government's Western Australian Rangeland Monitoring System (WARMS) beyond 2024. The primary purpose of WARMS remains to detect change in the condition and trend of the extensive rangelands across Western Australia. The Department of Primary Industries and Regional Development (DPIRD) aims to align WARMS with the move to risk-based monitoring and assessment outlined in DPIRD's Framework for Sustainable Pastoral Land Management.

Regular reviews of monitoring methods, collaboration with industry stakeholders and governing bodies are required to ensure the system's robustness and relevance for management of public lands.

A revision of DPIRD's grassland field site-selection and data collection protocols is presented with two main goals: (1) to improve monitoring effectiveness by aligning sites with key pastures and broad ecosystem types identified in ecological State and Transition models (Richards et al. 2023), and reducing the total number of sites monitored; and (2) to modify site spatial configuration and align data collection with national standards for fractional cover data collection, while maintaining longitudinal continuity with the WARMS program. The co-location of nationally comparable sites with suitable WARMS sites would be an efficient way to provide the ground measured data needed for calibration of remotely sensed fractional cover estimates, if the changes in data collection protocols prove compatible with previous WARMS condition trend detection. Methods for using remote sensing data to directly monitor rangeland condition and degradation risk will be explored.

In 2024 we began a field program of monitoring pasture condition using the existing WARMS site layout in tandem with the star transect layout for cover measurement in the Kimberley region of Western Australia. Data from the two transect configurations will be analysed to assess the practicality of substituting the existing WARMS measurement layout for the star layout without compromising the long-term trend detection.

Introduction
A revision of DPIRD's grassland field site-selection and data collection protocols is required because of DPIRD's desire to assist with the collection of SLATS data for contribution to the national database (Barnetson et al. 2017, Sparrow et al. 2020). There is also recognition that maintaining continuity with the existing WARMS program and data within available resources is valuable and worthwhile (Watson et al. 2007, Reeves et al. 2023).

A variety of methods are used in Australia to access ecological conditions including: % or relative cover using remote sensing (Than et al 2022, Scarth 2012, Ali 2016, Barnetson et al. 2017); ecological monitoring/validation on a tiered system (i.e. some sites visited more frequently than others) (Sparrow et al. 2020); SLATS (QDES 2022), and; landscape function analysis (Tongway and Hindley 2004).

Using WARMS data, we can determine rangeland condition trend over time and tree/shrub crown cover across a range of ecosystems (or states) (Novelly et al. 2008). The major causes of condition change events are seasonality, grazing, fire and flood. Time since fire is also a factor, and not currently considered; however, if it was decided that it was of value, high-quality spatial fire scar data could be incorporated into this dataset.

Instances where we have been able to detect or infer condition change at WARMS sites are relatively rare. This is because condition change generally occurs over an extended time period and requires more than one driver (i.e grazing pressure and seasonal rainfall). We have a large existing dataset that could be used to estimate *how many* times an event is likely to occur within a given period of time. The results could be used to inform the revisit and reporting cycle required to detect those changes, but this cycle is likely to be more influenced by resource availability and timelines.

DPIRD is intending to improve the method for allocating monitoring sites with consideration of geographical distribution and stratified to be representative of key pastures as identified during the development of the Land Condition Standards. A link to remote sensing is envisaged, so that the existing sites are validation and ongoing on-ground monitoring sites as part of a (yet to be developed) remotely sensed cover/condition system.

We have set out to ensure that the new data collection system will be comparable with the previous system by using initial measurements of collected at WARMS sites using both WARMS and SLATS transect layouts (Craig and Thomas 2008, Muir et al. 2012) to assess if the datasets are comparable or if there is a step change in the frequency of perennial pasture species occurrence.

Our objectives are:

- to improve monitoring effectiveness by aligning WARMS sites with key pastures and broad ecosystem types identified in in ecological State and Transition models
- to modify site spatial configuration and align data collection with national standards for fractional cover data collection, while maintaining longitudinal continuity with the WARMS program
- reduce the total number of long-term sites monitored, where possible without compromising the longitudinal data

Methods
The method and practicalities were discussed internally prior to collecting data from WARMS transects and SLATS star transect at 13 sites in 2024. We grouped the existing Kimberley grassland sites to determine

the number of sites for statistically robust analyses of key and non-key pasture groups identified during the development of the Kimberley Land Condition Standards (Fletcher et al. 2022).

WARMS grassland sites were shortlisted for field data collection early in 2024, targeting relatively stable sites categorised as Wet-dry tropical eucalypt woodlands of the Kimberley (Richards et al. 2023) or Pindan pastures (Craig and Thomas 2008, Ryan et al. 2013).

The orientation of SLATS transects is fixed, whereas existing WARMS sites may be any orientation. The layout for ratings of presence/absence of perennial species in 100 quadrats (0.49m^2) on the star transects is 33 on each transect, plus 1 random. Some sites did not include the 100th quadrat.

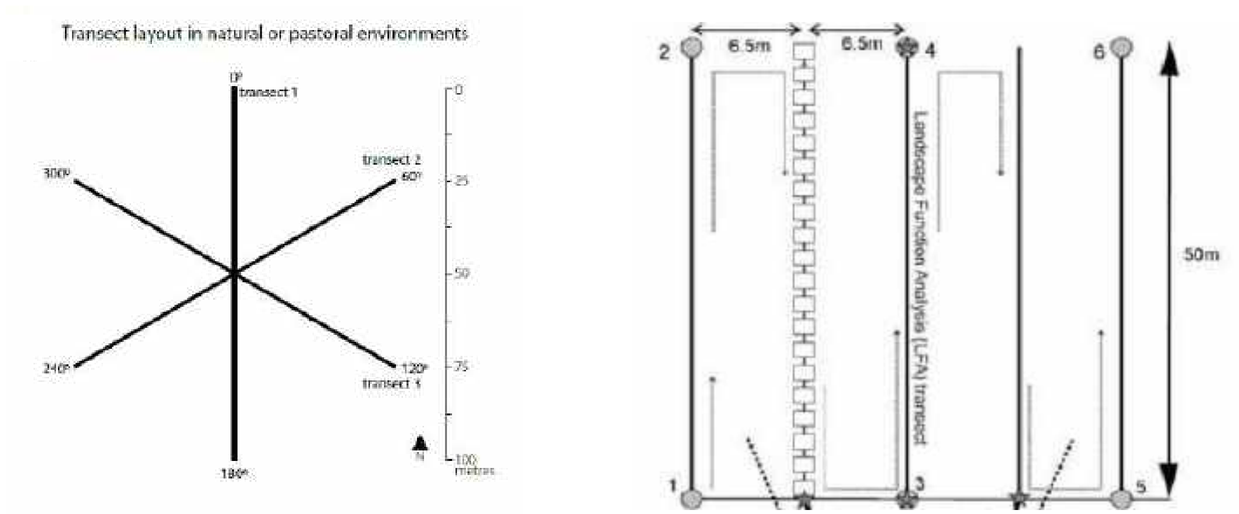

Figure 1. SLATS star transect layout with orientation (Muir et al 2012) (left) and WARMS transect layout (Craig and Thomas 2008) (right).

Data were collected from the WARMS transects then the SLATS transects were centred over the WARMS site and data collected from the SLATS transects.

Preliminary analysis of the data collected in 2024 is in progress using the Bray-Curtis method (K. Reeves pers. comm. 2024).

GIS and analysis of remotely sensed data will be used to select WARMS sites that meet the SLATS site criteria (P. Ramzi pers. comm. 2024), while maintaining longitudinal continuity with the WARMS program. Fractional cover data collected by DPIRD on pastoral leases cannot be displayed on the public TERN site without permission of the lessee, however, the applicable data collected are uploaded to the national TERN database for use in deidentified applications.

Quantifying a change in data collection methods involves several steps to ensure that the new method provides comparable and reliable data (Caughley and Sinclair 1994, Specht et al. 2015, Kaplan et al. 2021). Steps used in our approach are listed below:

1. **Baseline Establishment:** extensive data has been collected using the current WARMS method in rolling three-yearly assessments from 1994-2020. This will serve as the baseline for comparison. Parallel data collection is in progress using the SLATS site layout method and the current method during a transition period (2024-2025) that will be used to establish a preliminary dataset.

2. **Comparative Analysis:** A side-by-side comparison of data collected simultaneously by both methods is in progress and will be used to help identify systematic differences. Statistical tests (e.g. paired t-tests) will be used to determine if there are significant differences between the datasets from the two methods. Exploratory work is in progress.
3. **Calibration and Adjustment:** Calibration curves or adjustment factors will be developed to align the new method's data with the baseline data as required. Correction factors will be applied to the new data if systematic biases are identified.
4. **Error Analysis:** Error metrics such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Bias will be calculated, if necessary, to quantify the differences. The uncertainty associated with both methods will be assessed to ensure that the new method's uncertainty is within acceptable limits. The new method's uncertainty should not exceed that of the previous method unless justified by significant cost, time, or coverage advantages. For example, if the WARMS method has a standard error (SE) of 5%, the new method needs to be within this range or correctable using calibration models if biased. Acceptable MAE or RMSE might be ≤10% of the average quadrat counts in test sites.
5. **Validation:** Validating the new method with independent data sources or through external benchmarking will not be possible within the scope of this study, as the data are unique. Cross-validation by splitting the data into training and validation sets will be used to verify the robustness of the new method when enough data are collected to allow this.
6. **Longitudinal Studies:** Change detection techniques will be used to identify any significant deviations that might result from the method switch, if required.
7. **Documentation and Reporting:** The process, including the rationale for change, methods used for comparison, calibration, and error analysis will be documented and peer-reviewed internally and in scientific papers such as this to validate the approach and ensure transparency.
8. **Implementation of New Method:** Gradual implementation of the new method will not be possible, due to labour and expertise availability. The implementation of the new method is planned for completion in the WA grasslands in 2025, subject to DPIRD resources and priorities, and the results of a review of existing WARMS sites that are considered suitable for SLATS (in progress). Establishment of an ongoing regular data analysis system will be considered, so that issues arising from implementation of the new method are detected early and necessary adjustments can be made.

Results

Existing sites grouped according to pasture type

380 existing WARMS sites were considered and categorised according to key and non-key pasture groups set out during development of the Land Condition Standards for the Kimberley. One WARMS site was dropped from categorisation as it is the sole example of Lovegrass alluvial plain pasture in the dataset and lacks similarity to other pastures (Reeves et al. 2023). Pasture groups included in the development of state and transition models for the Kimberley included black soil plain pastures, frontage grass pastures and ribbon grass pastures. Pastoral value (categorised from very low (<2.5 cattle units (CU)/km^2) to high (>8 CU/km^2), fragility (after Craig and Thomas 2008) and suitability for remote sensing (Mundava et al. 2015, Ali et al. 2016) were discussed for each group. High pastoral value pastures suitable for remote sensing include marine plains and black soil plains, characterised by relatively low tree cover with generally good condition pastures that are fairly 'uniform'; low value examples include rocky and inaccessible country that is unlikely to be grazed by cattle Recommendations for consideration regarding the number of sites required for future monitoring are presented in Table 1.

Table 1. Existing WARMS sites grouped according to pasture characteristics

Pasture group	No. sites	Comment/s on pastoral value, fragility, other	Action to be considered
Hills/hard spinifex pastures	0	Low value, low fragility, suitable for remote sensing	None
Black soil plains pastures	137	High value, low fragility, suitable for remote sensing	Reduce, investigate which to keep and where to install under-represented 'states'
Frontage grass pastures	28	High value, high fragility	Increase to ~35
Ribbon grass pastures	99	Moderate value, high fragility	None
Coastal plains pastures	20	Range of values, range of fragility, localised, pastures in this group are very different from each other, some would be suitable for remote sensing	Investigate further
Pindan pastures	36	Low value, may be more fragile than previously published due to tussock grass component	None
Soft spinifex pastures	35	Low value, may be less fragile than previously published, suitable for remote sensing	None
Curly spinifex pastures	21	Low value, low fragility, probably suitable for remote sensing	Increase to ~30
Curly spinifex-annual sorghum hill pastures	3	Very low value, probably suitable for remote sensing	Drop entirely or increase

Summary of frequency data collected in 2024

Frequency data from 17 sites including that presented in Figure 2 below will be used for initial comparative statistical analysis. The clustered bar graph compares the frequency of desirable plant species, the frequency of quadrats without perennial plant species and the frequency of burnt quadrats, across the 17 sites assessed using both site layouts. The x-axis represents monitoring sites labelled sequentially, the y-axis indicates the frequency percentage (0 to 100) for the analysed variables, and the z-axis separates the data by variable and site layout. This set includes data from 4 sites collected in 2020, prior to method development discussions.

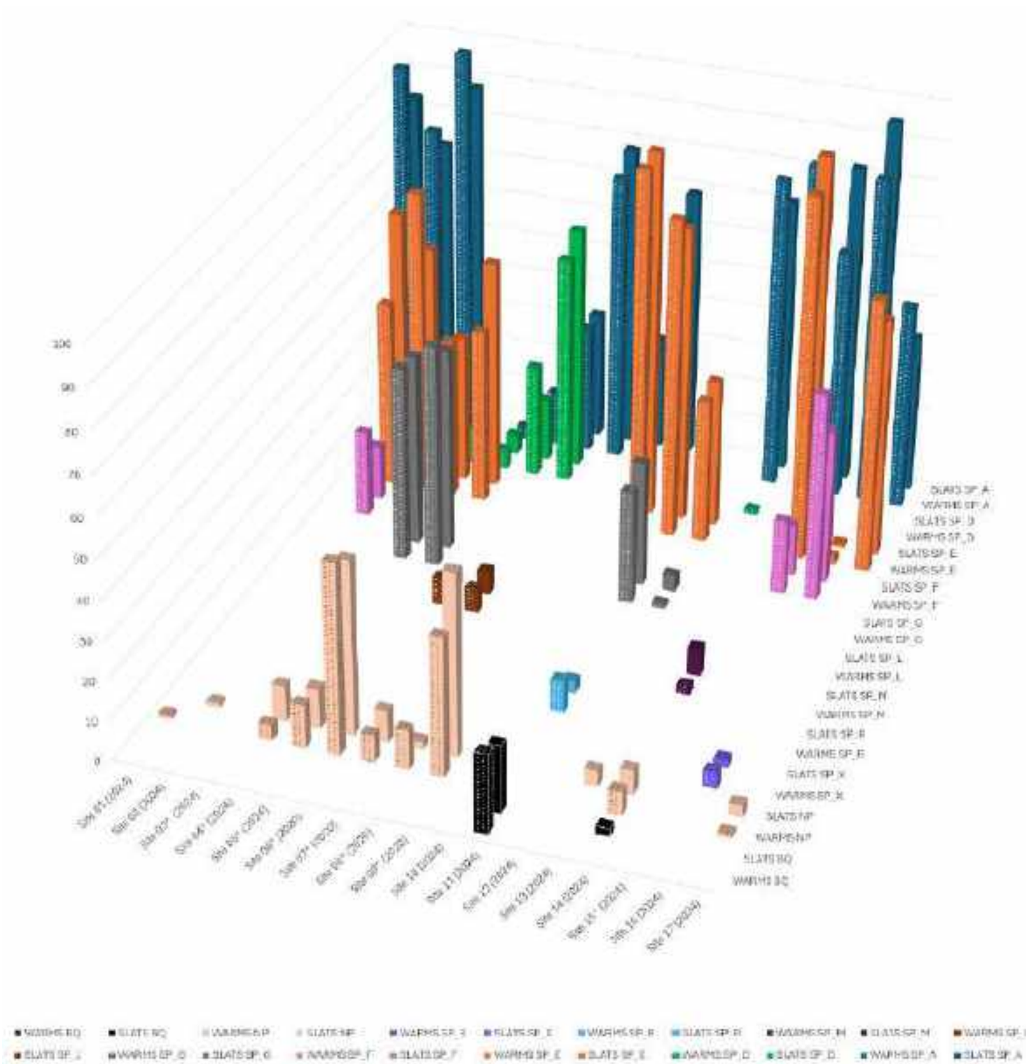

Figure 2. Comparative frequency data from sites assessed to date (*frequency data from 99 quadrats)

Discussion

We plan to collect additional data from shortlisted sites in 2025 to add to the comparative dataset.

Some SLATS star transect data may not be suitable for the TERN dataset, but will still be useful in this review and comparison with WARMS site data (P. Ramzi pers. comm. 2024).

Methods for using remote sensing data to complement on-ground monitoring of rangeland condition and degradation risk will be explored as part of this project, and may be useful in some pasture types for assessing the optimum number of on-ground data collection sites required and informing the optimum length of the epoch (revisit interval) required within our parameters to detect change.

The documentation of the change in the data collection method will allow the practicalities of substituting the existing WARMS measurement layout for the SLATS star layout without compromising the long-term trend detection to be quantified and analysed, which may assist other long-term ecological studies outside of the project area.

Establishment of an ongoing regular data analysis system is recommended to detect issues arising from implementation of the new method early, so that necessary adjustments can be made.

Use of commercial rumen boluses to evaluate hot and cold weather impacts on cattle grazing rangelands

Key words: humidity; livestock; sensors; humidity; wind

Abstract

Cold and hot temperatures can impact cattle health and wellbeing while grazing rangelands. Commercial rumen boluses can now remotely provide an indication of body temperature as well as an index of water intake. Ten 2-year-old Corriente heifers were monitored using smaXtec classic rumen boluses during June-August 2023 and January-February 2024 in a 312-hectare rangeland pasture near Prescott, Arizona USA. Reticular temperature measurements with and without proprietary adjustments for drinking water as well as activity indices were recorded every 10 seconds and reported as 10-minute averages. For analyses, temperatures were averaged hourly, every 3 hours and every 24 hours. During both summer and winter water-intake adjusted reticular temperatures (ART) varied by 0.6 C, and it was highest during late evening (1800 to 2159 hours) and lowest in the morning (0900 to 1159 hours). During the summer, ART was more closely associated with wet bulb globe temperature (WBGT) than air temperature, thermal heat index (THI), relative humidity and weather measures on an hourly basis. On a 24-hour basis, ART increased as WBGT and THI increased during the summer. During the winter, ART was most closely related to ambient temperature (AT) on an hourly basis. On a 24-hour basis during the winter, ART decreased during windy days, and ART initially increased with higher relative humidity and then decreased when relative humidity was over 70%. Estimated daily water intake decreased during periods of higher relative humidity during both summer and winter. Rumen boluses appear to be a useful tool to remotely monitor and study cattle responses to hot and cold weather while grazing extensive rangeland pastures.

Introduction

Livestock are regularly exposed to heat and cold stress, and impacts of predicted climate change will likely adversely affect animal wellbeing and productivity during the near future (Polley et al. 2013). Cattle must maintain a narrow range of core body temperature for optimal health. Extended exposure to high temperatures, relative humidity and solar load increase the risk of heat stress occurring during the summer (Shephard and Maloney 2023). A rise in core body temperature often followed by behavioral changes in water intake, feed intake, and activity occur during heat stress. If heat stress persists, negative effects on production, reproduction, and immune responses are known to occur (Lees et al. 2019a).

In the winter, cold stress can occur when animals are unable to maintain homeothermy due to low temperatures or wind chill (Shepard and Maloney 2023). Cattle exposed to extended cold stress, can experience a change in physiological processes, behavior, and hormone regulation, which may negatively impact performance (Wang et al. 2023) Despite, current climate trends and the public's concerns over animal welfare little research has been done to understand the extent of heat or cold stress for cattle grazing rangelands.

Rangelands are vast and often contain rugged terrain, which makes observations of cattle well-being difficult and labor intensive. Recent development of on-animal sensors, such as global positioning systems (GPS), accelerometers, and other devices, as well as the internet of things have facilitated real-time remote monitoring of the activity and health of livestock on rangelands (Nyamuryekung'e 2024). A rumen temperature bolus with radio frequency identification worked as a non-intrusive proxy for core body temperature to identify heat load in feedlot cattle (Lees et al. 2019b). The objective of this proof-of-concept study was to evaluate the effectiveness of a commercial rumen temperature bolus for monitoring the behavior and well-being of cattle in response to summer and winter weather conditions grazing a central Arizona rangeland.

Methods

The study took place at Deep Well Ranch (DWR) located 16 km north of Prescott, Arizona, United States. The study pasture NDP encompasses 312 ha with an elevation gradient of 1,460 to 1,520 meters. Deep Well Ranch falls within the Cold semi-arid (Bsk) of the Köppen climate classification and has an average annual precipitation of 487mm. The terrain is primarily rolling hills dominated by perennial grasses of black grama (*Bouteloua eriopoda* (Torri)), dropseed (Sporobolus spp.) and purple three-awn (*Aristida purpurea* Nutt).

A total of 28 registered 2-year-old Corriente heifers grazed the study pasture. Ten of the 28 heifers were randomly selected and administered smaXtec Classic Boluses (Graz, Austria) on April 7, 2023. The boluses recorded four metrics: reticular temperature (RT), adjusted reticular temperature (ART), activity index, and a water intake index. These metrics were measured every 10 seconds then averaged into 10-minute intervals, except water intake which is averaged into a single 24-hour value. Adjusted rumen temperature is a measure of reticular temperature excluding temperature changes from drinking events. All metrics except RT use proprietary algorithms to calculate the indices. SmaXtec boluses use long range Bluetooth to communicate with a base station, which sends data in real time to the internet using a SIM card with a cellular network.

All weather data were collected at the Prescott Regional Airport, which is 7 km from the study pasture. Ambient temperature (AT), relative humidity (RH), wind speed and solar load were recorded at 5-minute intervals. Thermal Heat Index (THI) was calculated using equations from Hahn et al. (2009), and Wet Bulb Globe Temperature (WBGT) was calculated using equations from Clark et (2024).

Both the smaXtec and weather data were averaged into 3-hour and 24-hour intervals from of June 1, 2023, to August 28, 2023 (summer) and from January 5, 2024 to February 29, 2024 (winter). The smaXtec and weather information was compiled into two data sets, one for 24-hour averages and another consisting of eight, 3-hour time periods within a day.

For the 3-hour data, an independent repeated measures analysis was performed for each combination of weather and smaXtec metric. Summer and winter analyses were conducted separately. The analyses were completed using PROC MIXED in SAS (Littell et al., 2006). The covariate structure was autoregressive, AR(1). The independent variable was one of the weather metrics (ambient temperature C°, relative humidity, solar load, THI, WBGT or wind chill). The dependent variable was one of the smaXtec metrics (RT, ART, or activity index). Heifer was the subject for all analyses. Linear, quadratic and cubic effects for each weather metric were evaluated. The best fitting models were selected based on the smallest Akaike Information Criterion (AIC) score (Littell et al., 2006).

For the 24-hour data, the same approach was used for the summer and winter analyses. An independent repeated measures analysis was performed for each combination of weather and SmaXtec metrics. The covariant structure was again autoregressive AR(1). The independent variable was one of the weather metrics, and the dependent variable was one of the smaXtec metrics. The subject was heifer. Linear, quadratic and cubic effects were evaluated for each separate weather metric.

Results

Summer

Using 3-hour data, RT and ART were nearly the same in early morning and late at night (Fig. 1). A clear divergence between RT and ART occurred mid-morning (06:00 to 08:00) when RT and ART decreased. During late afternoon and evening, RT and ART increased. Reticular temperature experienced a larger drop than ART in the morning. The best fitting model for ART was a cubic relationship with WBGT ($P<0.001$). Initially, ART dropped as WBGT increased. Adjusted reticular temperature then gradually levelled out and increased when WBGT was greater than 15º. The second-best model for describing changes in ART was a cubic relationship with RH ($P<0.001$). The cubic relationship indicated that ART rapidly increased from 0% to 40%, then ART continuously declined until 85% RH at which ART increased again. The activity index showed a clear diurnal grazing pattern with higher levels in the morning and evening (Fig. 2). The best fitting model for activity was a cubic relationship ($P<0.001$) with RH. Modelled activity levels steadily increased as RH increased up to 50%. If RH was greater than 50% any increases in the activity index were gradual. A negative linear relationship ($P<0.001$) with solar load the second-best model for describing changes in the activity index.

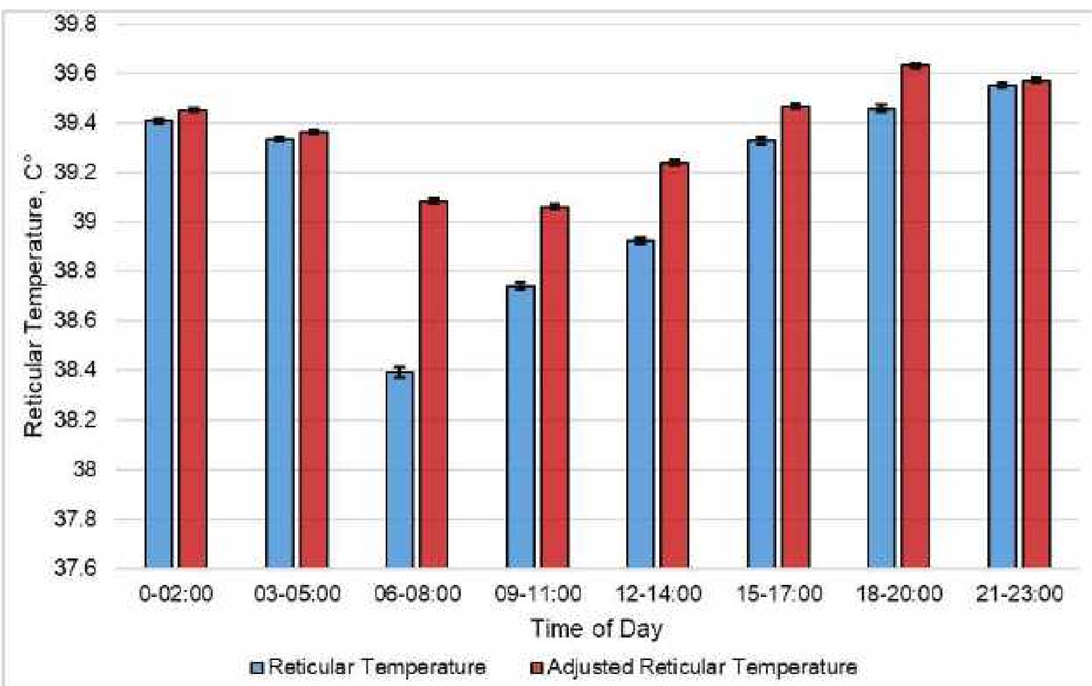

Figure 1. Least-square means of reticular temperature (RT) and adjusted reticular temperature (ART) averaged for each 3-hour period during the summer period. Error bars represent standard errors.

Using 24-hour averages, the best fitting model for ART was a quadratic relationship with WBGT ($P<0.001$) The model suggested that ART decreased when daily WBGT was less than 16. However, ART increased if daily WBGT values were greater than 16. The THI was the second-best predictor of ART with a positive linear relationship. As THI increased, ART increased. The water intake index decreased linearly with increasing RH ($P<0.001$). Days with the highest water intake had the lowest relative humidity. The second-best weather metric for modelling changes in the water intake index was a linear relationship with solar load with a linear relationship ($P<0.01$). The water intake index increased with increasing solar load.

Winter

Like the summer study, RT and ART were similar in early morning and late at night (Fig. 3). Both RT and ART started decreasing at 06:00 and reaching a low between 09:00 and 11:00 then increasing in the afternoon. A quadratic relationship ($P<0.001$) with ambient temperature was the best model for describing changes in ART using 3-hour data. As AT increased to 2°C, ART also increased, but at warmer temperatures ART began to decrease. There was also a quadratic relationship ($P<0.001$) between ART and wind chill with a quadratic relationship. Adjusted reticular temperature increased until wind chill reached zero, after zero ART declined with increasing wind chill. The best fitting model for the activity index (3-hour data) was a quadratic relationship with wind speed ($P<0.001$). The activity index increased with increasing wind speed until approximately 6 m/s. At higher wind speeds the activity index began to decline.

The best fitting model for ART using 24-hour data was a cubic relationship with wind speed ($P < 0.01$). The model suggested ART gradually increased with increasing wind speed until 5 m/s. After wind speeds surpassed 5 m/s, ART increased more rapidly. The activity index was also related to wind speed using 24-hour data. Activity increased linearly ($P<0.001$) with wind speed. Like summer, the water intake index was related ($P<0.001$) to relative humidity (quadratic relationship). Water intake was lower at higher levels of humidity.

Discussion

The higher values of ART compared to RT during midday demonstrate the proprietary algorithm used in ART helps account for drops in reticular temperature resulting from drinking water. The temperature of the drinking water was cooler than RT, thus consuming water lowered RT. Values of ART appear more consistent than RT during periods when cattle normally drink. Thus, ART should be a better metric than RT to use as an estimate of core body temperature. However, neither ART nor RT fluctuated by more than 1°C daily. As mentioned by Shephard and Maloney, (2023) homeothermy of cattle can fluctuate by 1°C daily and varies between species, seasons, and lifestyle stages, which creates difficulty for establishing a "normal" range for core body temperature. Therefore, cattle in this study likely did not experience heat stress. More research is needed in an area with hot temperature lasting for longer durations than central Arizona, as cool nighttime temperature at the study site would likely mitigate heat load. Higher ART values were observed during periods with a higher WBGT, which suggests ranchers in the region should monitor WBGT rather than just ambient temperature or THI to identify periods with increased risk of heat stress.

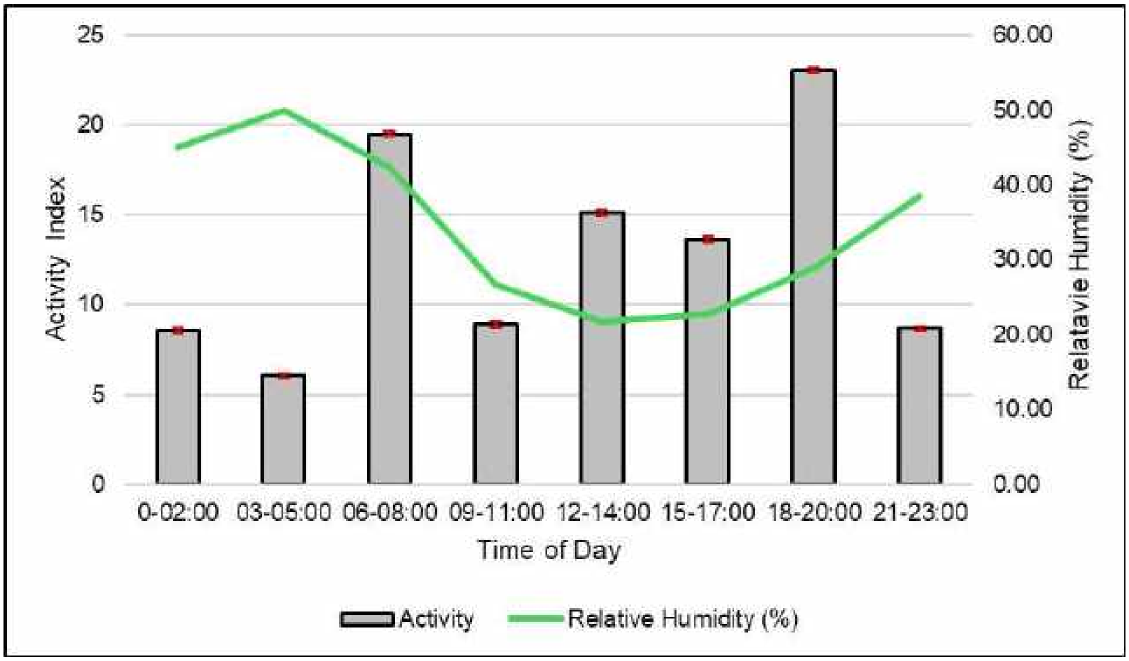

Figure 2. Relationship between the smaXtec activity index and relative humidity throughout the day during using 3-hour data. Columns are the least-square means of the activity index, and the error bars represent standard errors. Values are averages of the entire summer study period.

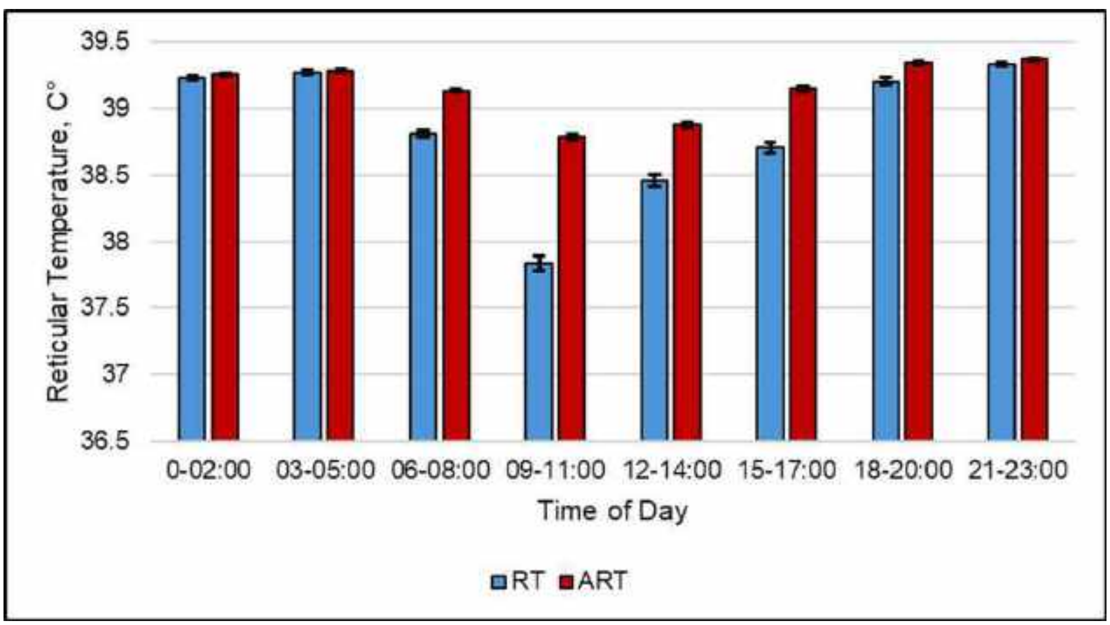

Figure 3. Least-square means of Reticular Temperature (RT) and Adjusted Reticular Temperature (ART) during 3-hour periods averaged over the winter study period. Error bars represent standard errors.

Relative humidity was related to many of the smaXtec bolus metrics in both 24-hour and 3-hour summer data sets. We found the strong association of RH and smaXtec metrics to be surprising because humidity is typically low at this Arizona study site. We speculate the reason RH is so influential is due to the association with monsoonal weather patterns. Periodic rains and cloudy weather occur during the monsoon season (July and August), which likely reduces solar load and ambient temperature. The water intake index decreased when RH levels increased throughout the study. Days with higher RH are correlated to wetter days in the region. During periods of high RH, there may have been moisture on the vegetation, potentially reducing cattle water demand.

During the winter, AT was useful for modelling adjusted reticular temperature within a day. However, wind and relative humidity were more associated with ART than other weather variables on a daily time scale. Wind speed was associated with daily activity changes. Estimated water intake appeared to decrease during periods of higher relative humidity. The impact of wind, relative humidity, and temperature suggest storm events likely influence cattle behavior and ART (a potential proxy for core body temperature) on rangeland during winter months. In this study, cattle appeared to either adapt to cold conditions or were not exposed to cold conditions long enough to result in cold stress. There were no apparent periods when cattle ART decreased for a sufficient time to suggest cold stress. If these boluses are to be used for detecting cold stress, more research in an area with colder conditions than central Arizona is needed.

The combination of a core body temperature metric (ART, adjusted reticular temperature) and an activity index were recorded every 10 minutes and the boluses reliably transmitted the data daily. This technology is promising and shows potential to monitor the well-being of cattle grazing rangelands throughout the summer and winter. The smaXtec rumen boluses worked well with very few issues. This sensor has potential for ranchers and researchers remotely monitor rangeland cattle behavior and core body temperature, but more research is needed in other locations and with other cattle breeds.

Acknowledgements
The authors would like to thank Bob Burris (Ranch Manager) and Deep Well Ranch for the use of the study site and cattle, as well as logistical and financial support for this research. The study was conducted in accordance with the New Mexico State University Institutional Animal Use and Care Committee (protocol numbers 2303000200 and 2308000468).

Construction of a 200-year annual domestic livestock distribution geographical dataset for Australia for the pre-digital era 1788 to 1980.

Irvine, SA[1,3]; Carter, JO[2,3]; Stone, GS[1,3]

[1] Grazing Land Systems; [2] Remote Sensing Centre, [3]Queensland Department of the Environment, Tourism, Science and Innovation, Brisbane, Queensland 4001, Australia.

Key words: Livestock; grazing distribution; pastoral history

Abstract

Domestic livestock statistics across all Australian jurisdictions have been collected since 1788. Cattle, sheep and horse numbers for the period were digitised from paper sources. Statistical district boundaries were also digitised from mapping sources for each year and coded to link to the digitised livestock records. Estimation of pre-European vegetation, natural waters, the development of stock water areas (bores, small dams), irrigation (fodder crops and pastures) and protected areas were used to distribute livestock within each statistical district for each year.

This work focuses on historical data as part of an undertaking to produce a comprehensive Australian high resolution time series map (1km2 grid) of livestock from 1788 to 1980. Such data is of use in grazing system models and other applications such as estimating long term methane emissions to help understand the long-term impacts of domestic livestock grazing pressures on the landscape and atmosphere.

This data collection shows a decline in data quality, due to the declining number and increased areas of statistical districts reporting livestock population. The results document the expansion of domestic livestock in area and numbers from first settlement and the probable distribution at a finer scale.

Introduction

Providing an estimate to historical grazing distribution within Australia will provide better understanding and background to the current environmental impacts. Climate variability and grazing pressure on the rangelands are well documented in McKeon et al. 2004 p 19, along with impacts on the Great Barrier Reef (Lewis et al. 2021), changes in native pasture composition (Dixon 1892; Carr and Turner 1959a; Harrington et al. 1979; Rolls 1981 pp 111,129), scrub and/or woody regrowth (Rolls 1981 p 185; Wilson 1990) and soil degradation (Carr and Turner 1959b; Rolls 1981 pp 129, 246). This dataset will facilitate exploration of issues such as land clearing, woodland thickening and methane emissions (Hempson et al. 2017). Domestic livestock within this paper refers to only horses, cattle and sheep, with feral livestock numbers not being included.

This work focuses on historical data prior to 1980 as part of an undertaking to produce a comprehensive Australian high resolution time series map of livestock from 1788 to current for use in grazing system models such as AussieGRASS (Carter et al. 2000). To this end, annual livestock population data that was available for all Statistical Districts was acquired and digitised. Mapping sources that showed the statistical districts or similar spatial entities were collected and used to estimate likely spatial boundaries at the time of collection. Later a disaggregation method was used, that proportioned the livestock population in each statistical district, in each year, to likely grazing densities that would be experienced. These are shown as an animal equivalent estimate per kilometre (AE km2).

Methods

Livestock numbers for each jurisdiction (six States and two Territories) were digitised from historical records and followed the progression of European land management throughout the 19th century (Fig. 1). Many of the livestock statistics were not continuous, and temporal gaps at the statistical district level were common. In these years, livestock totals for the jurisdiction were provided and used to estimate numbers for the statistical districts based on a percentage breakdown from the years where recorded data were present.

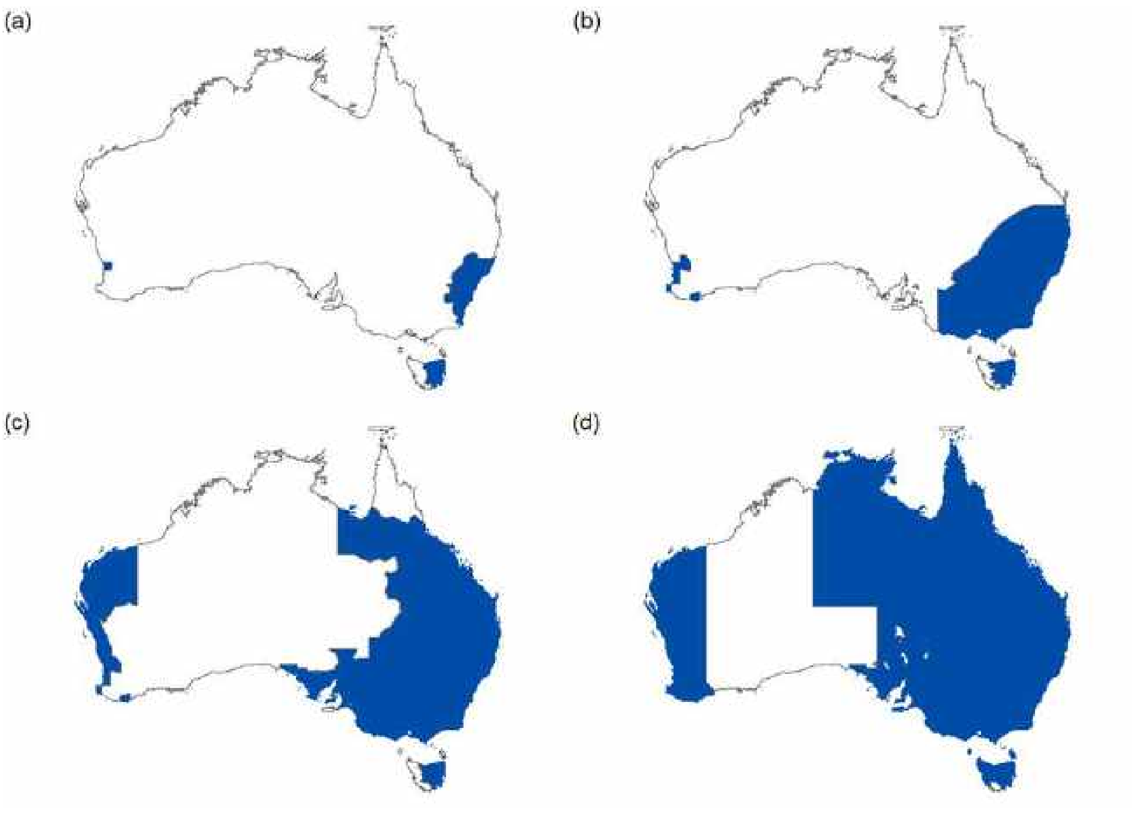

Fig. 1. The statistical districts shown in blue that were created within Australia by (a) 1830;(b) 1850; (c) 1870; and (d) 1890. The continent was fully covered by 1891, excluding major saline areas.

Mapping was based on maps used at the approximate time of the original data collection and where possible the same spatial entity as described in the textual records (i.e. local government area, police district, county etc). The spatial boundaries were subsequently captured by GIS using current digital cadastral information as a basis. The livestock numbers were converted to a common unit being dry adult equivalents (450kg cow or horse). Sheep numbers used a conversion of 7 sheep to 1 adult equivalent, with horse and cattle numbers being assumed as the same adult equivalents (Stone 2004 p194).

A common map code was added to the livestock (tabular) and statistical district data (spatial). This allowed a spatial join to be performed within ArcGIS Pro (Environmental Systems Research Institute 2024), creating a yearly spatial dataset showing the relevant livestock data within a spatial boundary. A heuristic livestock distribution was generated via ArcGIS Pro to downscale the livestock record for each statistical district for any given year. The distribution was based on a grazing land class that estimated the grazing pressure likely to occur in the statistical district based on the grazing land class and availability of water. The full methodology including the historical background, data sources, mapping references, and the determination of land grazing classes and associated land development features is described in Irvine et al. (2024).

Results

A median livestock distribution for all years from 1788 to 1980 is shown in Fig. 2. Biannual distribution maps are shown in Irvine et al. (2024). It is also shown that from the natural state of grazing lands, approximately 992,905 km2 of Australia had been improved by 1980 via clearing, water improvements and fencing, enabling an increased livestock density across the continent.

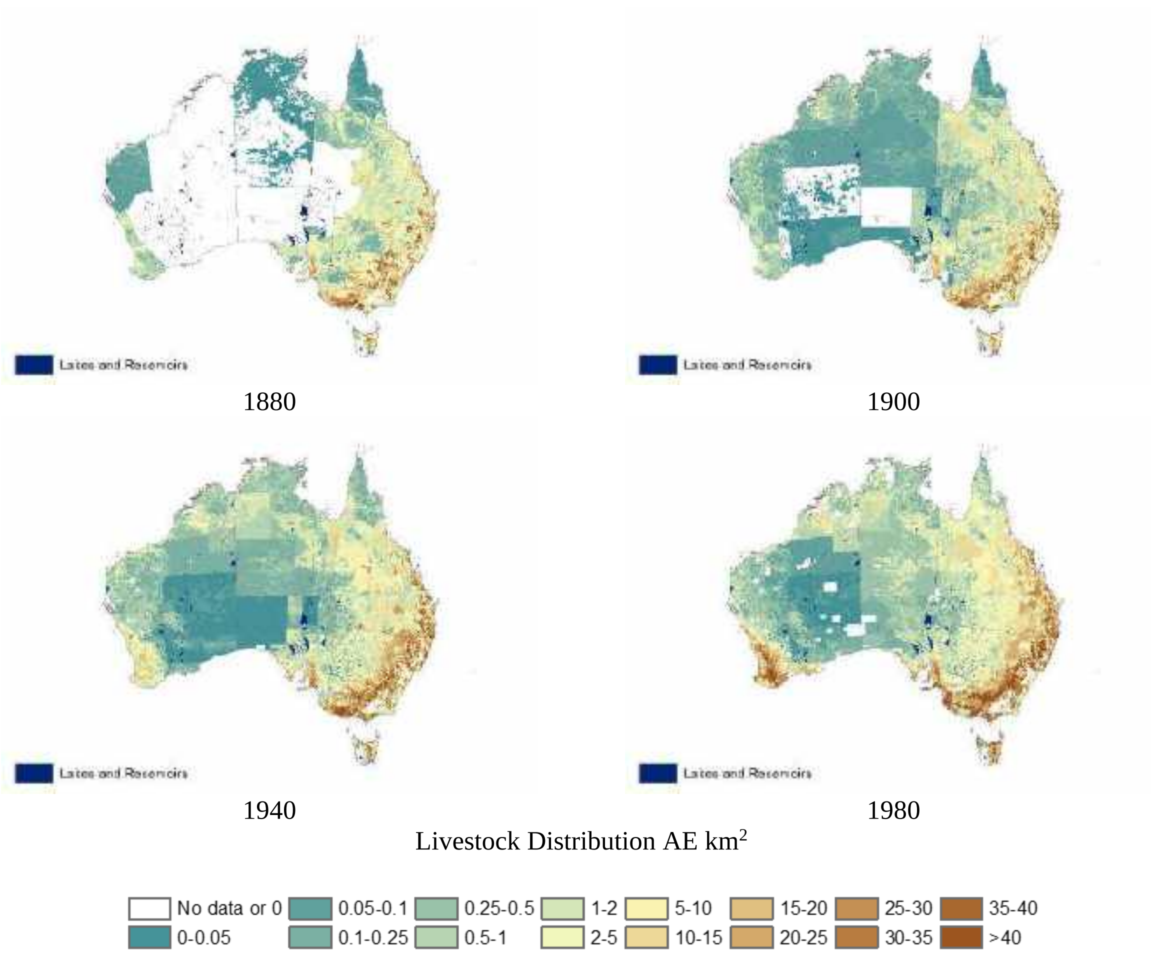

Fig. 2. Livestock distribution calculated for selected years.

In contrast to the continuous land improvement and increased livestock population, the statistical districts being used have decreased in number (Fig. 3) and are larger in area due to recent local government area amalgamations.

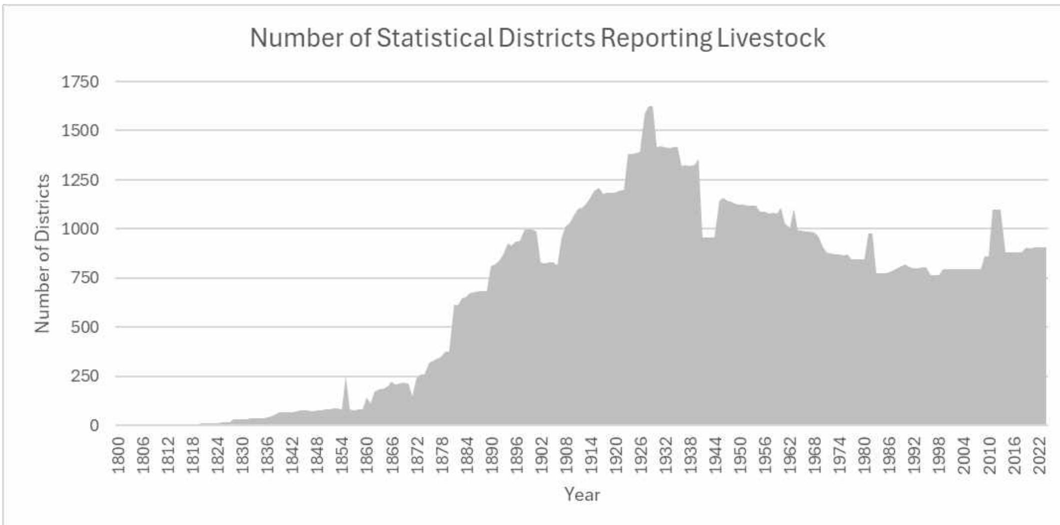

Fig. 3. The number of statistical districts reporting livestock have generally been declining since the 1920's.

Discussion

This study has accumulated all readily available Australian livestock population numbers collected at a statistical district scale, in a standardised format, proportioned to likely grazed areas and presented at a 1km resolution. However, significant gaps and limitations still exist due to the absence of records and/or inability to find all records.

The dataset generated from this analysis is a step in the process of estimating historical total grazing pressure, extending knowledge to previously unknown areas. It provides a standard baseline for any investigation to any aspect of Australian historical livestock populations, providing a grazing distribution to any spatial area.

The statistical record is being seen as degrading in quality mainly due to the amalgamation of pastoral statistical districts in recent years (Fig 3.), leading to a current discussion on the suitability of livestock data for analysis (Fordyce et al. 2023). This has likely led to changes and the development of new methodologies for the collection of livestock statistics, as noted by the Australian Bureau of Statistics (2024).

Key words: buffel grass; central Queensland; site data; GRASP model; calibration

Abstract

Inter-annual rainfall variability across Queensland, Australia, is among the highest in the world. This variability coupled with episodic periods of drought and flood and highly variable forage supply pose major challenges for grazing management in Queensland. Since the mid-1990s, researchers have successfully used historical and current pasture data with the GRASP biophysical model to simulate pasture growth in the grazing lands of northern Australia. The FORAGE online system provides a unique combination of pasture modelling (GRASP model), remote sensing and climate forecasts to support grazing land and environmental management decisions. Here we look 'back to the future' to build on previous research, transfer our past knowledge and experience in modelling grazing systems to new researchers, and use the traditional, highly valued but resource-intensive site data to improve the GRASP land type models used in the FORAGE decision support system. Four fenced sites were established in regionally dominant Brigalow softwood scrub and Brigalow blackbutt buffel grass (*Cenchrus ciliaris* cvv. Biloela, Gayndah) pastures. We use detailed soil, pasture and rainfall measurements collected over three years (2020 – 2022) to represent key biological and physical pasture processes in the GRASP model. Across the years, the sites varied in rainfall (3 – 138% above long-term median), average buffel grass dominance (69 – 98% of total yield), peak pasture yield (2742 – 4343 DM kg ha^{-1}) and sward nitrogen yield (19 – 34 kg N ha^{-1}). We use this data to improve the FORAGE modelled estimates of long-term buffel grass pasture productivity in the broader Brigalow softwood and Blackbutt land type pastures in central Queensland. This will inform grazing and environmental land management decisions that promote both sustainable natural resource use in grazing lands and profitable grazing industries.

Introduction

Grazing with beef cattle and sheep is the dominant land use in Queensland, Australia, occupying nearly 86% of Queensland's 173 million hectares. Gross value of production from cattle and calves was estimated to be $6.6 billion and 35% of Queensland's primary industry commodities in 2024 – 25 (Queensland Government 2024). Almost 25% of the Queensland herd (~2.5 million cattle) grazes over 11.1 million ha in the Fitzroy Basin (MLA 2022).

Buffel (*Cenchrus ciliaris* L.) grass is an introduced strongly tufted, erect (60 – 100 cm tall), perennial, summer-growing grass that occurs on range of soil types containing reasonable fertility. The productivity, adaptation and drought tolerance of buffel grass make it the most widely established sown pasture in Queensland, estimated to be 'dominant' on 5.8 million ha (Peck et al. 2011), and a major contributor to the Queensland grazing industry.

The considerable inter-annual and decadal rainfall variability experienced in Queensland (Klingaman et al. 2013), and associated major temporal variability in forage supply, pose a major challenge for the sustainable and profitable management of grazing businesses (O'Reagain and Scanlan 2013). Since the mid-1990s, researchers have successfully used historical and current pasture data with the point-based GRASP model (McKeon et al. 2000) to simulate pasture growth in the grazing lands of northern Australia. The GRASP pasture growth model has been calibrated for over 100 native pasture sites across Queensland (Day et al. 1997) and has been widely used in the rangeland environments to predict year-to-year variability in forage supply and to estimate safe carrying capacities in the highly variable climate of northern Australia (e.g. Day et al. 1997; Walsh and Cowley 2011; Whish et al. 2014). However, there is little site data to predict pasture growth of long-term established buffel grass pastures in Queensland.

The Queensland Government developed an operational online information system – FORAGE – to facilitate decision support for grazing and environmental land management practices (Zhang and Carter 2018). The FORAGE system provides land managers with property-scale information relating to rainfall, ground cover, soil erodibility, land types, tree density, seasonal climate outlooks and pasture growth simulated using the GRASP grazing system model.

Here we look 'back to the future' to build on previous research, transfer our knowledge and experience in modelling grazing systems to new researchers, and use the traditional, highly valued but resource-intensive site data to calibrate buffel pasture GRASP models at four locations within 75 km from Emerald (23°31´S and 148°09´E), central Queensland. In this paper we outline the systematic approach for buffel grass model calibration, review the calibration results and extend the site models over time. We briefly discuss the use of the buffel site calibrated models across similar soil types and pastures, and the potential use of calibrated models to improve the FORAGE modelled estimates of long-term buffel grass pasture productivity in the broader Brigalow softwood and Blackbutt land type pastures in central Queensland.

Methods

Paired SWIFTSYND sites were established on the regionally dominant Brigalow blackbutt (sites 'A', 'B') and Brigalow softwood scrub (sites 'C', 'D') (State of Queensland 2022) buffel grass (cvv. Biloela, Gayndah) pastures at three grazing properties within 75 km from Emerald, central Queensland.

Fenced (to exclude livestock, wildlife and feral grazers) 30m x 30m sites were established during November (B, C, D) and December (A) 2019 on good condition buffel grass pastures that were established approximately 15 years previously. Preparation of the sites each year involved using brush cutters to remove dead material to 5 – 10 cm and remaining litter before spring rains.

The extensively cleared, Brigalow blackbutt sites (A, B) were established on hard setting, sandy clay loam to medium clay (brown sodosol) soils, whilst the Brigalow softwood scrub sites (C, D) were established on periodically cracking, light – medium clay to medium heavy clay (black vertosol). All sites were densely covered with medium tall (34 – 40 cm) Gayndah dominant buffel pastures, with the taller (~1.0 – 1.5 m) Biloela buffel grass a third of the pasture sward at the D site (Table 1).

Detailed pasture measurements were collected four times a year over 2020 – 2021 period using the methodology of Day and Philp (1997). Following the declaration of 'La Niña' an extra year of sampling

(2022) was undertaken at all sites to optimise the capture of potential growth when not water-limited. The measurements taken at each site provide the minimum information required to determine pasture and soil parameters for the pasture growth model GRASP. Site measurements included pasture yields and composition (‘Gayndah’ buffel, ‘Biloela’ buffel, ‘Other grasses’, ‘Legumes’, ‘Dicots’), heights, grass basal area, cover and plant nitrogen (N) content. Climate files for each site were obtained from SILO (Jeffrey et al. 2001) and combined with site-specific daily rainfall data (tipping bucket rain gauge). Soil water, Colwell phosphorus content, soil profiles and bulk density measurements were also collected at each site. In this paper we used three years of data in the calibration of ‘B’ and ‘D’ sites, and only the first two years of data in the calibration at ‘A’ and ‘C’ sites.

The GRASP model was used to simulate pasture production at the fenced buffel pasture sites through calibration using GRASP Calibrator (version 1.33 Build 7177). A systematic approach for model calibration (Scanlan et al. 2008), and the adjustment of parameter values to achieve the ‘best fit’ between model and site data, was employed to ensure key biological and physical pasture processes were well represented in the GRASP model. The latest versions of GRASP CEDAR (version 2.1.04 date 30/11/2023) and CEDAR default parameter file (cedardefault_v_2_1_03.prv dated 19/1/2024) were used. Long-term (1876 – 2024) annual (1 Oct- 30 Sep) ‘Year Type’ seasonal analysis for rainfall and pasture growth percentiles were derived for each calibrated site model using historical climate data.

Results

Site description

Annual rainfall (Jan – Dec) varied across the sites with the B and D sites receiving less rainfall than A and C sites during the study, however, all sites received rain in 2021 and 2022 that was well above (31 – 138%) their long-term median annual rainfall (Table 1). The long-term average annual rainfall and year-to-year variability (co-efficient of variation) for the sites ranged from 579 mm and 0.36 at B site to 619 mm and 0.40 at A site.

During the relatively drier 2020 growing season, peak pasture and N yield were greatest at the Brigalow blackbutt B site (Table 1). During the wetter year (2021) the peak pasture yield was greatest at the Brigalow softwood scrub C site, however, a similar peak pasture yield and the highest N yield was reached at the Brigalow blackbutt A site (Table 1). Peak pasture production during the 2021 growing season was broadly reflected in the similar or lower sward N yields compared to the drier year.

Site calibration

The GRASP model was used to simulate pasture production at the four buffel pasture sites through calibration using GRASP Calibrator and the adjustment of parameter values to achieve the ‘best fit’ between model and site data. Calibration commenced using the Queensland Government’s Brigalow blackbutt and Brigalow softwood scrub land type parameters used in the FORAGE online system (Zhang and Carter 2018).

The average annual rainfall at the four buffel pasture sites during the study (2020-2022) was in the long-term 60-100th percentile for all sites (Table 1). The four calibrated buffel pasture models when compared with observed (measured) data were a good to very good fit for pasture yield (Total Standing Dry Matter, TSDM kg ha^{-1}, Fig. 1 & Table 2), fair to moderate fit for soil water, with none to moderate agreement for N yield in TSDM (Table 2).

Long-term median annual pasture growth was highest at the Brigalow blackbutt B site, with pasture growth at the other sites being 2% (D), 6% (A) and 10% (C) less than site B (Table 2). The long-term median pasture growth for the calibrated models was higher than the respective FORAGE Brigalow blackbutt land type models but lower than the respective FORAGE Brigalow softwood scrub land type models (Table 2).

Discussion & Conclusions

Detailed pasture production data collected at the Brigalow blackbutt and Brigalow softwood scrub buffel grass pasture sites was successfully used to calibrate the GRASP model. Model calibration included adjustment of the Queensland Government's Brigalow blackbutt and Brigalow softwood scrub land type parameters values to achieve the 'best fit' between model and site data.

*Only first 2 years data **2022 data being analysed

The four buffel calibrated models produced reasonably good fits (R^2 0.84 – 0.92) to observed TSDM data, aligning with the R-squared (R^2 0.92) achieved for a model calibration of buffel grass site near Moura, central Queensland (Peck et al. 2017). Poor to moderate agreement of the four calibrated models to soil water (R^2 0.15 – 0.70) and N yield of standing dry matter (R^2 0.0 – 0.66) were achieved during this study. Discrepancies between observed and predicted values of soil water are likely to be due to difficulties accessing sites during the wet periods and sampling dry, crumbly soils, rather than any site-specific impediment. The poor to moderate fits of modelled data to measured N yield at the three of the four Gayndah-dominant buffel pasture sites (A, B, D) were worse than that achieved for the calibrated Brigalow softwood scrub buffel grass model (R^2 0.57) at Moura where Gayndah buffel contributed only 22% of pasture yield (Peck et al. 2017). The higher observed than predicted N yields achieved during this study could be due to the ability of Gayndah buffel to respond quickly to rain and flower early whilst the flowering plant continues to produce extra N-rich leaves and new shoots. GRASP has a relatively simple calculation of N limitation so both the limitations of soil fertility and climate can be represented in simulations of pasture growth. The observed high N yields as an indicator of pasture quality are also an important driver of animal production. Further work is required to develop a dynamic N sub-model in GRASP that will enable representation of buffel grass species that exhibit high N yields in simulations of pasture growth and animal production.

The long-term (1890 – 2024) median pasture growth for the four calibrated buffel grass models (4739 – 5022 DM kg ha^{-1}) was slightly higher than the simulated long-term (1995 – 2014) annual pasture growth (4166 DM kg ha^{-1}) of grazed buffel grass pasture near Moura (Peck et al. 2017). The long-term median pasture growth for the calibrated buffel grass pasture models were approximately 10% more than FORAGE Brigalow blackbutt buffel but 30 – 35% less productive than the FORAGE Brigalow softwood scrub buffel model. Further consideration of site-specific characteristics and the adequacy of the study sites to represent the broader Brigalow softwood scrub and Brigalow blackbutt buffel pastures in central Queensland is required.

This work has provided an opportunity for a senior researcher to successfully transfer their knowledge and experience in modelling grazing systems to a new researcher, and demonstrate the value of the traditional, resource-intensive site data to calibrate buffel pasture GRASP models to inform and improve the FORAGE modelled estimates of buffel grass pasture productivity in central Queensland.

Table 2. Linear relationships (R-squared) between observed and predicted Total Standing Dry Matter (TSDM kg ha^{-1}), soil water for layers 1 (0 – 10 cm), 2 (10 – 50 cm) and 3 (50 – 100 cm), and nitrogen yield (kg N ha^{-1}) for the four Brigalow blackbutt and Brigalow softwood scrub buffel pasture calibrated models. Long-term (1876 – 2024) annual (1 Oct – 30 Sep) seasonal analysis 'All Years' median pasture growth (kg ha^{-1}) simulated for each calibrated buffel site model and for FORAGE Brigalow blackbutt and Brigalow softwood scrub land type models.

On-animal sensors: measuring grazing cattle behaviour under two different supplement strategies

Freitas-Kirk, T[1], Eyre, KE[1], McCosker KD[1], Prada e Silva, L[1]

[1]Queensland Alliance for Agriculture and Food Innovation, The University of Queensland, Qld 4343, Australia.

Key words: protein supplements; on-animal sensors; monitor behaviour

Abstract

Protein supplements are a common approach to address nutrient deficiencies in rangeland cattle. On-animal sensors have emerged as an alternative for measuring individual cattle behaviour, including supplement intake, in near real-time without human intervention. This study aimed to study the combination of on-animal sensors to monitor behavioural changes in response to varying levels of individual supplement consumption.

Fourteen Droughtmaster heifers were fitted with a wireless ear tag (WelfareTag™ HerdDogg), GPS collar (i-gotU GT-600), and rumen bolus (SmaXtec® Classic Bolus). They co-grazed a 10-ha paddock from 20/9/22 to 13/12/22. In two consecutive periods, they were offered different supplementary high-protein diets, expected to vary in palatability. During period one (days 1-42), heifers received 300 g/d of a low-intake supplement (26% CP, 5% Urea), and during period two (days 43-85), they received 1000 g/d of a high-intake supplement (30% CP, 4% Urea). Data were analysed using R (version 4.3.1) and RStudio with a linear mixed-effects model ('lmer'), each parameter was considered individually.

During period 2, heifers spent 1.7 times more time at the feed trough than in period 1 ($p<0.001$), suggesting increased supplement consumption. Grazing activity was not significantly higher in period 1 than in period 2 ($p<0.1$). Resting time in period 1 decreased ($p<0.1$) but travelling times increased ($p<0.01$). Rumen temperature and rumination index were lower in period 1 ($p<0.05$, $p>0.1$), while oestrus index was higher in period 1 compared to period 2 ($p<0.001$). Counts of water-drinking events were higher in period 2 ($p<0.001$).

In conclusion, behavioural differences were detected by on-animal sensors associated with greater supplement intake. The adoption of sensors for continuous monitoring enhances nutritional, grazing, and reproductive management in extensive rangelands, supporting better decision-making about target supplement intake and improving grazing behaviour and pasture utilisation.

Introduction

The Australian beef production operations are predominantly pasture-based, with grazing cattle facing challenges such as fluctuating pasture quality and quantity during the dry season, mineral deficiencies in the soil, and unpredictable rainfall that affects forage availability. To address these challenges and minimize production losses, supplemental feeds are often provided during the dry season to supply essential proteins, minerals, and energy (Bowman & Sowell, 1997). However, the effectiveness of supplementation relies on animals consuming the target amounts. In recent years, precision livestock management has emerged, allowing producers to monitor the health, welfare, and productivity of animals in near-real-time. On-animal sensors are central to this approach, enabling continuous, remote monitoring of livestock behaviour 24/7. These sensors, attached directly to the animal, can record a range of behaviours, offering valuable insights for managing extensive cattle systems. This study aims to integrate three types of on-animal sensors—a wireless ear tag, a rumen bolus, and a GPS tracking collar—to monitor behavioural changes in grazing cattle in response to varying levels of individual supplement intake. We hypothesize that these sensors can detect behavioural adaptations to different supplementation levels.

Methods

The study was conducted from September 20 to December 13, 2022, at the University of Queensland, Gatton, Australia. Fourteen Droughtmaster heifers, aged 11-13 months (average weight: 268 ± 32.7 kg, range: 194-320 kg), were allocated to a 10.11 ha paddock with unimproved pasture African star grass *(Cynodon nlemfuensis Vanderyst)* at 85% coverage and Queensland blue grass (*Bothriochloa pertusa*) and provided mineral and protein supplements for 12 weeks. The experiment was divided into two periods. During period 1 (days 1-42), heifers were offered a low-intake supplement (target: 300 g/head/day) containing 12% crude protein, 5% urea, and 5 MJ/kg energy (PBA Feeds, Toowoomba, Qld). In period 2 (days 43-85), they received a high-intake supplement (target: 1000 g/head/day) with 19% crude protein, 4% urea, and 8 MJ/kg energy (PBA Feeds, Toowoomba, Qld).

Each heifer was fitted with three on-animal sensors: 1) Wireless ear tags (WelfareTag™, HerdDogg) with Bluetooth technology recorded the animal's presence and the received signal strength indication (RSSI). A threshold of ≥ -50 dBm was used to predict time spent at the feed trough, based on prior studies(reference if appropriate); 2) GPS tracking collars (i-gotU GT-600) recorded the heifers' positions at 10-second intervals to monitor grazing patterns and classify heifers' activity; and 3) Rumen boluses (SmaXtec® Classic) recorded temperature, oestrus index, rumination rate, and water intake, with a temperature drop below 38°C indicating drinking events. The classification of cattle activity into three different categories – grazing, resting, and travelling – was based on the criteria established by Augustine and Derner (2013). Data were collected over 85 days. A linear mixed-effects model ('lmer') in R (version 4.3.1) was used for statistical analysis of the longitudinal data with repeated measures.

Results

Wireless ear tag

During period 2, heifers spent an average of 8 minutes at the feed trough, compared to 4.5 minutes in period 1, representing a 1.7-fold increase ($p < 0.001$). This indicates a significant increase in supplement consumption during the second period (Table 1).

GPS tracking collar

Grazing activity was higher in period 1 (21.37%) than in period 2 (17.37%), but this reduction in grazing time was not statistically significant (Table 1, $p > 0.1$). When comparing the two different periods, it was found that the resting time in period 1 (69.18%) was lower than in comparison period 2 (77.62%), however that difference was not significantly different (Table 1, $p > 0.1$). Travelling time was increased in period 2 (3.57%) compared to period 1 (2.85%), this difference was significantly different (Table 1, $p < 0.01$). Additionally, there was a statistical difference in travel time between the two periods ($p < 0.01$), with heifers in period 2 travelling 0.54% more than during period 1.

Rumen bolus

The results showed that there was a significant (Table 1, $p < 0.05$) increase in the heifers' reticulo-rumen temperature by 0.12°C in period 2 compared to period 1. During period 1, the average reticulo-rumen temperature was 39.08°C, while in period 2 it was 39.17°C. The rumination index of heifers showed no significant difference in response to the two different supplement target intake (Table 1, $p > 0.1$). Although the average rumination index in period 1 was 26,6540 and in period 2 it was 27,734, it was found that the increase between the two periods was not statistically significant ($p > 0.1$). The oestrus index had a significant influence on the two different periods. The results showed that heat index increased significantly (Table 1, $p < 0.001$) from period 1 to period 2. In period 1, the average oestrus indicator was 3.19 units, while in period 2 it decreased to 2.35 units. The heifers in period 1 had a higher oestrus index on the day of oestrus than in period 2. In Period 2, heifers under the higher supplement intake had a lower average of oestrus index. The results for the cumulative number of water-drinking events per day showed a significant increase of 1.64 in period 2 compared to period 1 (Table 1, $p < 0.001$). During period 1, the average cumulative water drinking events per day was 3.17, while in period 2 it increased to 5.23.

Table 1 contains detailed data on the difference in measured behaviours: time spent at the feed trough, grazing time, resting time, travelling, rumen temperature, rumination index, heat index and counts of water drinking events, between the two periods.

Table 1 Difference in measured behaviours using on-animal sensors between the 2 periods.

Behaviours measured	Period		SEM	P-value
	1	2		
Time spent at the feed trough (min)	4.5	8.0	0.46	<0.001
Grazing time (%)	20.37	17.37	1.07	0.08
Resting time (%)	69.18	77.62	1.05	0.09
Travelling time (%)	3.06	3.60	0.09	0.002
Rumen temperature (°C)	39.08	39.17	0.02	0.015
Rumination index[1]	26654	27734	721	0.29
Oestrus index[2]	3.19	2.35	0.15	<0.001
Counts of water-drinking events	3.17	5.23	0.27	<0.001

Discussion

Supplemental feeding is a common strategy to enhance the performance of grazing beef cattle. However, traditional herd-based monitoring of supplement intake often overlooks individual variability in consumption and may not account for animals that do not consume the supplement (Bowman & Sowell, 1997). Precision livestock management can provide continuous near-real-time monitoring on an individual animal basis, rather than via herd-based information (Aquilani et al., 2022). In this study we combined the use of three on-animal sensors to continuously monitor 14 heifers, revealing significant insights into cattle behaviour and supplement intake.

The wireless ear tag recorded the predicted time spent at the feed trough, with cumulative counts of RSSI ≥ -50 dBm indicating that time at the trough increased by 1.8 times during the second period, which featured a more palatable supplement. This second supplement had nearly double the metabolisable energy (8 MJ/kg vs. 5 MJ/kg) and a higher protein content (30% vs. 26%), which likely contributed to its enhanced palatability and voluntary intake (Launchbaugh et al., 1997; McDowell, 1996). Previous research (Imaz et al., 2020, p. 8; Nkrumah et al., 2007, p. 2388; Oliveira et al., 2018, p. 634) has demonstrated that time spent at the feed trough has a strong positive correlation with feed intake. Our results are consistent with the previous work cited above and show that as the palatability of the supplement increases, the voluntary intake and predicted time spent at the feed trough also increase.

Our results showed that increased time at the feed trough corresponded with a reduction in grazing time, particularly during the second period, when the supplement provided an intake target of 1 kg/day per head. This decrease in grazing time is consistent with literature indicating that high-protein supplements can reduce grazing activity (Bargo et al., 2003). This effect is likely due to the substitution effect, where providing a higher amount of supplement reduces pasture intake and, consequently, grazing time. Bargo et al. (2003) reported that for each kilogram of supplement offered to grazing dairy cows, there was a reduction of 12 minutes in grazing activity.

The heifers averaged 72.44% and 77.62% resting time during periods 1 and 2, respectively, supporting previous observations that grazing cattle often exhibit significant inactivity (Swain et al., 2008). Additionally, we noted a statistically significant increase in travel time during the hotter second period, likely due to the heifers seeking shade, which was located 400 m from the feed trough. Period 2 was, on average, 4°C hotter than period 1, with maximum temperature ranging from 21.3°C to 37.6°C. The heifers displayed higher reticulo-rumen temperatures during period 2 (39.18°C) compared to period 1 (39.06°C). This increase may result from the animals' inability to dissipate sufficient metabolic heat (Becker et al., 2020) and the higher energy content in the feed, which also contributed to the increased rumen temperature in period 2. Kurihara (1996) also observed an increase in body temperature and respiration rate in dairy cows when comparing a low to a high-quality diet.

During the trial, the heifers were in oestrus for five days out of 50 in period 1 and two days out of 35 in period 2. Notably, predicted time spent at the feed trough decreased during oestrus ($p < 0.001$), corroborating findings by Reith et al. (2014) that report a 14.6% reduction in intake on oestrus days. The cumulative number of water drinking events also significantly increased by 1.64 times in period 2 ($p < 0.001$), suggesting that the heifers were compensating for heat stress by increasing water intake. Ahlberg et al. (2018) found that the water intake in feedlot steers increased when they were exposed to temperatures above 28.06°C. Weather conditions, particularly maximum temperature, significantly impacted the time spent seeking shade. The heifers spent an average of 18.42% of their time in the treed area during period 2, compared to only 6.18% in period 1.

In summary, this study confirmed the efficacy of on-animal sensors in monitoring individual cattle behaviours that affect supplement intake. The combined use of these technologies facilitated a nuanced understanding of how supplement consumption, grazing time, and environmental factors interact. Future research with larger herds and varying supplement types is recommended to further validate the applicability of on-animal sensors in pasture-based systems.

A quick meal plate index and its use as a decision-making tool for ranchers

Duarte, E[1]; Dieguez, F[2]; Pereira, M[1]

[1]Instituto Plan Agropecuario, Burges 3802, Montevideo, Uruguay, 11800; [2] Facultad de Veterinaria/UdelaR, Instituto de Producción Animal, Ruta 1 km 42.500, San José, Uruguay, 80100.

Key words: grass allowance, forage balance, extensive production systems, livestock management

Abstract

In Uruguay, the forage base that feeds our herds and flocks is natural grassland. Research in the last 20 years has shown the importance of working with a greater proportion of grass to improve animal performance and make our systems more resistant and resilient to climate change. However, to date there has been no tool that allows for simple grass budgeting that can be used by livestock ranchers without major complications. With this objective, an index called the "Meal Plate Index" (MPI) has been developed in collaboration with ranchers, which, by estimating forage availability by measuring it with a ruler and comparing it with forage requirements by category, objective and season, allows us to know how well we are doing with grass in relation to the productive objectives we are trying to achieve. In practice, the difficulty is in making the grass field measurements. For this reason, and to move towards general application, a simplified version has been developed which, by means of visual estimation with self-calibration of the height of the sward and calculation of the stocking rate of the farm, can quickly and easily provide an estimate of how full the feed plate is that the animals need. The MPI tool, in both its regular and "quick" versions, was compared against external information provided by a national ranchers' network. The tool was adjusted to account for average and extreme forage conditions (both scarcity and excess) during its development and testing phases. The impact of using this simplified tool will improve the performance of ranching systems and for our national herd.

Introduction

Uruguayan livestock farming is one of the main economic and land use activities (Paparamborda et al. 2023). The primary source of food for livestock on ranches is the native grassland, which is a heterogeneous resource, both in the seasons of the year (e.g. forage species and grazing management) and between years, due to climatic effects (Modernel et al. 2016). In this context, the Instituto Plan Agropecuario (IPA 2024) is the national extension agency for extensive producers, where it works with ranchers and other stakeholders on relevant issues for livestock production systems (Durate & Dieguez 2023). The IPA's activity is focused on extension activities, workshops and projects with producers and training activities on relevant topics for livestock production. Particularly, it is of interest to work in a participatory manner with the forage assignment at native grasslands in livestock production systems (Durate & Dieguez 2023). This issue is more relevant in open-air systems, dependent on variable and extreme weather conditions. Adaptive management (Darnhofer et al. 2010) is important in a context of climate change, to enhance production systems resiliency in participative processes (Dumont et al. 2020). Likewise, it is of interest of IPA to generate quick tools for diagnosing of feed offered and required to help decision making about the actual and projected stocking rate and animal allocation. The estimation of forage availability and animal demand, as key factor of system productivity (Paparamborda et al. 2023), are crucial issues that can be implemented with the use of new information and communication technologies local and international impulse (MGAP 2024, UN 2024). In this work is presented a methodology which the "Meal Plate Index" (MPI) was participatively developed, and further development for a "quick MPI", as prototype of an online decision-making tool.

Methods

The MPI tool was developed within IPA participative project, where 18 ranches participated in 8 field workshops by farm (one by season in a 2-year period). The MPI consists of the ratio between forage allowance and animal requirements (Duarte & Dieguez 2023).

In the first version of MPI, a spreadsheet with inputs like animals' number by category to calculate dry matter requirements, and paddocks grass height (GH) was developed. The GH was converted to DM offering by hectare using seasonal constants (250, 220, 250 and 215 kg DM/cm/ha for autumn, winter, spring and summer respectively; Duarte & Dieguez 2023). In those sessions training of farmers to data gathering, GH measurement skills, data input and results interpretation was carried out. To define cattle requirements, average forage availability was established according to the category and season (see Table 1). Also Stocking Rate (SR) was calculated using national definition of Gross Unit by hectare (GU/ha), being 1 GU the requirements of DM of a breeding cow with 380 kg of LV, that weans a calf by year (Berreta & do Nascimento 1991).

Table 1: Average forage allowance for cattle category by season expressed in kg DM by kg of liveweight (LW; Do Carmo et al. 2019).

Category	Autumn	Winter	Spring	Summer
Growing cattle (<300 kg LW)	3	3	2	3
Fattening cattle (>300 kg LW)	5	9	5	5
Breeding cows	5	4,5	6	5

In workshops instances, animals, paddocks and feed management information was discussed with stakeholders, according to MPI values. Some relevant workshops activity included the discussion with focus group of ranchers, analyzing together a particular farmer case, to achieve the adjusted SR (farm carrying capacity; Paparamborda et al. 2023) to cope climatic issues like drought episodes. To visualize results of MPI, ranges were defined values like a traffic light where values less than 0,6 had red color, ranges between 0.6 and 0.8 had yellow color, ranges between 0.8 and 1.2 had green color, and ranges more than 1.2 had brown color. These traffic light colors represent forage availability, but last range (>1.2) reflect a forage surplus with loss of quality, linked with pasture digestibility. In field workshops, ranch owners received other farmers in those activities, where seasonal field GH measurements, SR and MPI calculations were made, and finally discussions round were held to clarify grass and cattle management options to improve MPI, particularly in situations with values < 0.8. In other cases, where MPI was acceptable, success factors that explain results were also discussed inside focus group.

As a benchmark for tool use, MPI results were compared with external data from the farmers' information-sharing network, which provides monthly updates on grass availability, climate conditions, and cattle status (RING 2024).

Since, in the development and validation processes some issues were detected on data gathering (mainly pasture objective measurements with a ruler), further development was made towards an easier decision-making tool. A "quick MPI" was developed using a two-entry table, presented in the next section.

Results

Table 2 presents MPI values for autumn and for breeding cows. Since several categories and paddocks combinations can be considered, infinite tables can be presented. Table 2 must be read as an example of a particular situation.

Table 2: MPI values for breeding cows in autumn in a double-entry table format.

During project execution, farms with a "yellow" zone had lower forage supply than required and reduced their SR (e.g., selling culled cows) to transition to the "green" zone. Farms in the "green zone" could retain animals, sell tactically, and reserve paddocks while maintaining their status. Farms with a "brown light" used strategies like fattening culled cows and excluding paddocks for autumn reserves to transition to the "green" zone. However, these conditions, typical of prior spring-summer seasons, have been absent in several regions for years. In 2022/2023, a severe drought caused very low forage availability by autumn 2023 (INIA-GRAS 2024). Farms reduced SR (0.5–0.7 LU/ha), pasture heights rarely exceeded 4 cm, and MPI values were in "red" and "yellow" zones. Key tactical measures included selling animals, leasing land, and importing feed. Autumn paddock reserves for winter were not feasible, creating a winter forage deficit despite rainfall recovery. In 2023/2024, abundant rainfall (INIA-GRAS, 2024) led to record pasture growth in spring-summer and high forage availability by autumn 2024, with pasture heights of 7–10 cm and most MPI values in "brown" and "green" zones. Farms increased SR through animal retention, grazing sparse paddocks, and early protein supplementation. Strategic autumn reserves were unnecessary, as pastures maintained high heights, ensuring favorable winter forage conditions.

Discussion and Conclusions

Forage allowance is a key factor in improving the productive performance of systems (Do Carmo et al. 2019). In Uruguay, technical options to enhance productive and reproductive efficiency are well-known, a recent study by Paparamborda et al. (2023) indicates that producers often do not adopt these technologies due to various reasons. Molina & Álvarez (2009) argues that non-economic factors are associated with decision-making and determine technological changes. In this context, participatory work with producers is an appropriate and well-valued tool, where peer-to-peer knowledge exchange is productive (Do Carmo et al. 2019, Paparamborda et al. 2023). Furthermore, according to evaluations conducted during workshops in this study, the objective of peer exchange was achieved through the development and application of the MPI. This index, which is easy to implement, facilitates pasture monitoring and forage allocation for livestock. During workshops where MPI was applied, discussions extended beyond production objectives, encompassing the broader goals of the family-farm system. Various technical alternatives were outlined to improve outcomes and achieve specific goals. The MPI's design aligns in some aspect with the co-innovation approach (Paparamborda et al. 2023), encompassing three domains: social learning, monitoring and evaluation dynamics, and complex adaptive systems.

On the other hand, Carballo & Severi (2024) highlight that even forage is crucial for livestock production systems, pasture measurement is not a common practice among producers. This motivated the creation of a Quick MPI, where training the eye to estimate pasture height, alongside SR estimation, simplified situational diagnostics. MPI is a situational index where low values may result from below-normal pasture growth in previous seasons (e.g., due to lower rainfall) or from excessive forage demand caused by overstocking. Identifying the "why" is the first step in discerning potential solutions.

The MPI tool, in both its regular and “quick” versions, was compared against external information provided by a national ranchers' network called RING (RING, 2024). The tool was adjusted to account for average and extreme forage conditions (both scarcity and excess) during its development and testing phases.

The workshop environment facilitated the development of MPI, reflection, identification of alternatives, actions, and learning. This space for co-creation of knowledge accelerated adaptation processes for managing in uncertain and changing environments. In this regard, the MPI tool enhances group discussions by situating participants in the real-world context of their situation. When producers recognize they have a problem, it initiates technical change dynamics as they seek more information, plan alternatives, and select a course of action. Currently, a mobile application for Quick MPI is being developed, featuring simple data input (e.g., category, number and weight of animals, and pasture height by paddock). The goal is to scale this tool to a broader audience.

Quantifying ecosystem services: A conceptual framework for regenerative agriculture in Western Australia's rangelands

Jayasinghe, SL[1]; Thomas, DT[1]

[1]CSIRO Agriculture and Food, Private Bag 5, Wembley, WA 6913

Key words: Ecosystem services; net primary productivity; remote sensing; machine learning; InVEST model

Abstract

Rangelands and pastoral systems play vital roles in biodiversity conservation, carbon sequestration, and supporting livelihoods. However, their vast and heterogeneous landscapes pose significant challenges for assessing and managing ecosystem services (ES). This study aimed to develop a comprehensive framework to quantify the impacts of regenerative agriculture (RA) practices within these ecosystems, focusing specifically on Western Australia's rangelands. These practices offer a sustainable approach to enhancing ecosystem resilience, yet their effects on ES remain underexplored. The framework integrates the Integrated Valuation of Ecosystem Services and Trade-offs (InVEST) model, remote sensing technologies such as high-resolution satellite imagery, and machine learning (ML) techniques. These methodologies systematically map and assess key ecosystem services across different spatial scales, including provisioning (e.g., net primary productivity (NPP)), regulating (e.g., water dynamics), cultural (e.g., habitat quality), and supporting services (e.g., soil health). Using field and climate data from 2000 to 2023, along with satellite indices (NDVI, LAI), were used to calculate Photosynthetically Active Radiation (PAR) and Fraction of PAR Absorbed (FPAR), which are crucial for estimating Net Primary Productivity (NPP). Advanced ML algorithms, including Random Forest and Neural Networks, are employed to predict key ecosystem services. The framework supports the simulation, evaluation, and optimization of regenerative agriculture practices, thereby enhancing ecosystem resilience and promoting sustainable rangeland resource management. Forecasting ecosystem values in monetary terms, especially under regenerative agriculture scenarios, equips policymakers with tools to assess policy outcomes and advance sustainable land management in rangelands and pastoral systems. Despite its capabilities, persistent challenges such as data availability, the nuanced and context-specific nature of regenerative agriculture scenarios, and ethical considerations—such as community involvement in data collection—are critical for successfully implementing the framework.

Introduction

Rangelands, which cover approximately 40% of Earth's terrestrial surface, provide essential ecosystem services (ES), including biodiversity conservation, carbon sequestration, water regulation, food, and livelihood support for an estimated 200–500 million pastoralists worldwide (Alkemade et al. 2013; Maestre et al. 2022). In Australia, these vast arid and semi-arid landscapes support Indigenous communities, livestock grazing, and industries such as mining and tourism. However, rangeland ecosystems are increasingly threatened by overgrazing, invasive species, soil erosion, and climate variability, resulting in significant degradation (Gemechu and Dalle 2023). For example, 44% of grazing lands in northern Australia show signs of degradation, which compromise their ecological and economic functions, including the capacity to sustain biodiversity, store carbon, and maintain soil and water quality (Nielsen et al. 2020).

Regenerative agriculture (RA) presents a promising solution for restoring degraded rangelands (Khangura et al. 2023). Practices such as rotational grazing, greater tactical adjustment of carrying capacity (e.g. livestock sales, use of irrigated pasture systems), and landscape rehydration aim to restore soil health, improve water retention, and enhance biodiversity by fostering more diverse and resilient ecological systems (Jayasinghe et al. 2023; Lal 2020). However, assessing the impacts of RA on ES—such as carbon sequestration, biodiversity enhancement, and water retention—is complex due to the spatial and temporal variability inherent in rangeland ecosystems. Traditional assessment methods, including low-resolution remote sensing and qualitative surveys, lack the precision and scalability needed for effective evaluation (Kabir et al. 2020).

This study aimed to develop a conceptual modelling framework that integrates remote sensing (RS), Geographic Information Systems (GIS), and machine learning (ML), to assess the impacts of RA practices on ecosystem services in Western Australia's rangelands. By incorporating models such as Carnegie-Ames-Stanford Approach (CASA) and Integrated Valuation of Ecosystem Services and Trade-offs (InVEST), the framework facilitates precise, scalable, and localized assessments of ecosystem services. This approach provides detailed spatial and temporal data tailored to the unique conditions of rangeland ecosystems, addressing critical gaps in current methodologies. Ultimately, this research will offer actionable insights for sustainable rangeland management, enabling land managers and policymakers to make informed decisions that promote the long-term ecological and economic sustainability of rangelands.

Methods

A literature review identified key ES relevant to rangelands, such as soil organic carbon (SOC), water retention, and biodiversity, which were selected for their ecological and practical significance (Mashizi et al. 2019). These ES were chosen to assess the effects of RA practices, including rotational grazing, tactical stocking adjustments, landscape rehydration, and soil management (Jordon et al. 2022). Western Australia's rangelands were selected for their ecological importance, challenges related to land degradation, and representation of arid and semi-arid climates, enhancing the broader applicability of the framework. The framework applies RS, GIS, ML algorithms, and biophysical models to assess ES and link them to RA practices:

Ecosystem services assessment: High-resolution satellite indices (e.g., NDVI, LAI), combined with field data (e.g., soil properties, vegetation biomass), are used to monitor spatial and temporal variations in key ES indicators. The CASA model estimates Net Primary Productivity (NPP) to quantify vegetation growth and carbon fluxes. The InVEST model, in conjunction with ML algorithms, assesses carbon sequestration, water retention, biodiversity, and soil health. ML algorithms, and biophysical models (e.g., CASA, InVEST). All datasets are., RS data from Sentinel-2 and MODIS, harmonized for spatial and temporal consistency, serve as the foundation for ES mapping across rangelands.

Linking RA to ecosystem services: The effects of RA practices, such as rotational grazing and landscape rehydration, on ES are quantified using GIS and biophysical models. Changes in SOC, soil health, and water retention resulting from RA practices are mapped and analysed.

Model validation: Model outputs are compared with field-measured data (e.g., vegetation biomass, SOC), while uncertainty is assessed using Monte Carlo simulations and sensitivity analysis. This iterative process ensures robustness and adaptability to varying management practices and climatic conditions.

Results

The conceptual framework was developed to quantify key ES and assess the impact of RA practices on Western Australia's rangelands (Figure 1). The case study region will be selected based on its ecological significance and the ongoing implementation of RA practices. This approach highlights how RA practices, such as rotational grazing and landscape rehydration, contribute to the enhancement of ES and the resilience of ecosystems. The framework is currently in the conceptual stage, with full implementation planned for future studies.

Ecosystem service quantification

Carbon sequestration is estimated through both aboveground and belowground biomass, with NPP serving as the basis for SOC estimation (Lal 2004). RA practices, like rotational grazing, are expected to improve carbon storage by increasing SOC. Water retention is evaluated using a soil water balance model, integrating InVEST-driven evapotranspiration and water availability (Su et al. 2020). Improved soil health through RA practices like soil rehydration enhances water retention, which contributes to ecosystem resilience. Biodiversity is assessed using diversity indices (e.g., Shannon and Simpson), which are linked to NPP and floral density (Pla et al. 2011). RA practices are anticipated to increase biodiversity by promoting diverse plant communities. Soil health is evaluated by measuring soil organic matter, nutrient cycling, and improvements in soil structure (Doran et al. 1994). Soil health is a key indicator of RA’s success in promoting sustainable land management. Soil erosion is modelled using the Revised Universal Soil Loss Equation (RUSLE) (Renard 1995), while pollinator activity is inferred from NPP-driven floral density (Tylianakis et al. 2008). Greenhouse gas (GHG) mitigation is quantified by CO_2 sequestration and reductions in CH_4 and N_2O emissions (Joyce et al. 2013). GHG mitigation is enhanced by RA practices that improve carbon sequestration and reduce emissions from soil disturbance.

Visualization and trend analysis

The InVEST model and ML algorithms, including Random Forest (RF) and Convolutional Neural Networks (CNN), are employed to upscale ES metrics across larger spatial and temporal scales. High-resolution satellite imagery, in conjunction with field surveys, improves the accuracy of predictions and captures spatial heterogeneity (Burke et al. 2021). Tools such as Google Earth Engine and ArcGIS are used for spatial mapping and trend analysis to evaluate seasonal and long-term ES dynamics under varying climatic conditions.

Current status and future work

While still in the conceptual phase, the framework is designed to enable the spatial and temporal mapping of ES, allowing for future scenario evaluations and sensitivity analysis.

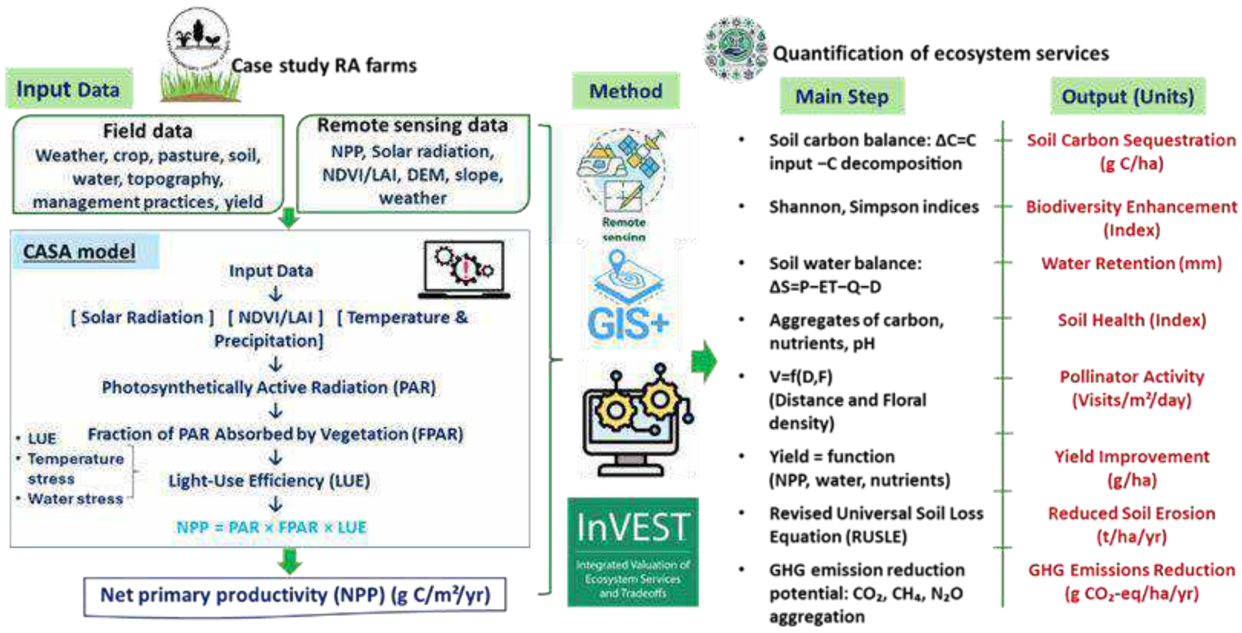

Figure 1. Conceptual framework for evaluating ecosystem services of regenerative agriculture in rangeland systems

Discussion

This study proposed a novel framework for assessing the impact of RA on ES in Australia's rangelands. By integrating RS, biophysical models, and ML, the framework enhances precision compared to traditional methods by accounting for regional variability and enabling scalability across landscapes (Kabir et al. 2020).

The selected ES—SOC, water retention, and biodiversity—are essential for ecological stability and effective land management. SOC plays a critical role in soil fertility and climate mitigation, while water retention contributes to climate resilience. Biodiversity, assessed through diversity indices, supports habitat quality and pollinator populations, both of which are vital in rangeland ecosystems (Lal 2004; Su et al. 2020; Pla et al. 2011). Previous studies (e.g., (O'donoghue et al. 2022; Jayasinghe et al. 2023) confirm the relevance and quantification potential of these services in RA systems, providing a strong basis for their inclusion in this framework. The framework directly informs RA decision-making by quantifying the impact of interventions on key ES. For example, rotational grazing can be evaluated for its effect on SOC and biodiversity through changes in NPP and species diversity indices. Tactical adjustments to carrying capacity, such as managing stocking rates or utilizing irrigated pastures, can be assessed for their influence on water retention and carbon storage across varying climatic and land-use scenarios. Landscape rehydration practices can also be linked to water retention improvements via soil moisture dynamics analysis from high-resolution remote sensing data.

The framework employs NPP to quantify carbon sequestration and link it to broader ecological processes. The CASA model estimates NPP using satellite and field data, providing regional estimates and addressing local variability (Zhu et al. 2017). This allows for region-specific customization, improving ES prediction accuracy by accounting for local environmental and land-use variability. The integration of ML algorithms, such as RF and CNNs, enhances the model's ability to capture complex, non-linear relationships, addressing landscape heterogeneity. These techniques have proven effective in ecological monitoring (Liu et al. 2018).

By integrating these tools, the framework helps land managers prioritize RA interventions based on their benefits and trade-offs, maximizing ES outcomes while considering landscape variability and resource availability. It can guide decisions on rotational grazing, soil health, and water retention strategies tailored to local conditions.

While the framework offers significant advantages, challenges remain, particularly regarding data quality and model uncertainty. Reliable field data is critical for model calibration, while uncertainty analysis—incorporating sensitivity and Monte Carlo simulations—addresses potential sources of error (McFarland et al. 2008). Successful implementation of the framework also hinges on collaboration with land managers and policymakers to ensure its practical applicability across diverse rangeland ecosystems. Despite these challenges, the integration of high-resolution data, advanced modelling techniques, and stakeholder engagement positions this framework a powerful tool for sustainable land management. It provides a solid foundation for evaluating RA interventions and enhancing ecosystem services in rangeland environments, offering valuable insights for land managers and policymakers.

Conclusion

This study proposed a comprehensive framework to assess the impact of RA on multiple ES in Western Australia's rangelands, including SOC, water retention, biodiversity, soil health, soil erosion, and pollinator activity. The framework integrates RS, biophysical models (CASA, InVEST), and ML techniques to quantify these services with high precision and scalability. It uses NPP as a key input in the InVEST model to estimate other ES. Despite challenges related to data quality, model calibration, and uncertainty, the framework provides valuable tools for optimizing RA practices, supporting sustainable rangeland management, and enhancing ecosystem resilience.

Predicting drought using remotely sensed vegetation cover

Leys, J F[1]; McDonald, SE[2]; Turnbull, GL[3]

[1] CSIRO, Black Mountain, Canberra, Australia; [2] NSW Department of Primary Industries and Regional Development, Orange, NSW Australia, [3] Western Local Land Services, Bourke, NSW, Australia.

Key words: Drought; Destocking; Decision Trigger; Groundcover.

Abstract

In Australia, land degradation caused by wind erosion and dust storms often occur during drought when vegetation cover is low. Destocking early is a critical management action that can reduce soil erosion; however, predicting drought to inform producer decisions regarding destocking is a complicated task. In Australia, drought is determined by several indicators, such as rainfall deficiencies, soil water, pasture growth, water availability, agricultural production, and community impact. Many of these indicators influence total vegetation cover (denoted as cover), which includes photosynthetic and non-photosynthetic cover.

This study uses a 22-year record (2001-2022) to investigate if a "trigger point", i.e., the month and cover level, can be identified that would potentially inform destocking four to six months before a drought cover (<20th percentile minimum monthly cover in summer) is reached. Twenty-four properties in western NSW rangelands were evaluated to determine the trigger month and trigger cover. The trigger month was August for 83% of properties. The drought cover ranged from 60% to 25%. The trigger cover ranged from 70% to 35%. Over the 22 years, 22% of years recorded drought cover. The method correctly predicted 80% of years with drought cover, i.e. those years below the trigger cover that had drought cover the following summer. The method failed to predict drought in six percent of years. In six percent of years, it predicted drought, but no drought occurred. The study demonstrates the practical application of a new tool to help land managers prepare for drought.

Introduction

Degradation of soils and vegetation is highly undesirable (Duniway *et al.* 2019). According to the United Nations Convention to Combat Desertification definition, land degradation can be caused by both human and climate factors (UNCCD 1994). Drought alone does not cause land degradation; the major cause is carrying too many animals for too long (McKeon *et al.* 2004). Maintaining cover is key to avoiding land degradation. Pasture production is low in drought, and ground cover declines, especially when stock numbers exceed the forage available and soil erosion increases. It has long been recognised that preventative early warning before the onset of drought would help land managers reduce livestock and unmanaged herbivore numbers before total vegetation cover (denoted as cover), which includes photosynthetic and non-photosynthetic cover, is reduced to levels that enable soil erosion (Childs 1973; McKeon *et al.* 2004; O'Reagain 2011). McKeon et al. (2004, p.22) state, "it is hard to imagine that any manager, if forewarned of a potential degradation event, would take the risk of animal losses, financial cost, and environmental damage by not reducing stock numbers early". However, knowing when to destock, referred to as a decision trigger, is a significant challenge that many authors have identified (Ratcliffe 1938; Condon 1992; McKeon *et al.* 2004; Hacker *et al.* 2010).

Accurately predicting the onset and termination of droughts is a major deficiency in drought prediction (Mishra and Singh 2011) because drought is a continuum (Van Loon *et al.* 2024). Several drought monitoring services exist in Australia, each providing information to assist decision-making. The Bureau of Meteorology (BoM) website has an interactive Australian Water Outlook tool (https://awo.bom.gov.au) with information on soil moisture, runoff, evapotranspiration, deep drainage, and precipitation. It also has a dedicated Drought page (http://www.bom.gov.au/climate/drought/) with information on rainfall deficiencies, soil moisture, water, and rainfall forecasts.

In New South Wales (NSW), the Department of Primary Industries and Regional Development (DPIRD) publishes an interactive tool called the Combined Drought Indicator (https://edis.dpi.nsw.gov.au/). It utilises the Rainfall Index (RI), Soil Water Index (SWI), Pasture Growth Index (PGI), and Drought Direction Index (DDI) with a multi-index approach. It tracks the onset (e.g. drought affected (intensifying)), duration and retreat of large drought events.

In the United States, the U.S. Drought Monitor (USDM) (https://droughtmonitor.unl.edu/) provides weekly maps of normal conditions, abnormally dry (D0), showing areas that may be going into or are coming out of drought, and four levels of drought: moderate (D1), severe (D2), extreme (D3) and exceptional (D4). It uses multiple data sources of streamflow, reservoir levels, temperature and evaporative demand, soil moisture, and vegetation health and blends this with drought impacts, field observations and local insight from a network of more than 450 experts.

This study aims to reduce soil erosion and land degradation by using satellite fractional vegetation cover data as a metric to set a decision trigger month and estimate the trigger cover (TC) level below which destocking should be considered for grazing properties in western NSW. Decision triggers (trigger) are designed to link cover data in this paper to a management action, i.e., consider destocking (Cook *et al.* 2016). Two triggers are presented: 1) the time of the trigger so management can be adapted, and 2) the cover threshold, i.e. a visual cue for the trigger, four to six months ahead of the drought.

Methods

Cover changes every month, and the ranges in cover change from property to property. As a result, each property is assessed for 1) which winter month is the best trigger, i.e. correlates with the following summer cover, 2) how many times the drought cover, that is, the cover measured in previous droughts since 2001 and defined as the 20th percentile of the 22-year monthly time series (DC) and how many times TC was recorded for the property over the 22 years, and 3) how many years were both TC and DC observed.

For 24 properties in the semi-arid rangelands of western New South Wales, Australia, a 22-year time series of monthly green (photosynthetic vegetation (PV), non-photosynthetic vegetation (NPV) and total vegetation cover (cover) for each property at 500m resolution was extracted from GEOGLAMM RaPP (hereafter called RaPP) (CSIRO 2024).

Drought cover, rounded to the nearest 5%. This coincided with the Millennium Drought (2002-2009) and the Tinder-box drought (2017-2020). The DC level was determined for each of the 24 properties. The trigger month, i.e., the month in winter that can predict DC the following summer, was determined using linear regression (E 1) for each winter month (June/July/August) cover (WC) against the month with the minimum summer cover (December/January/February) (MSC).

MSC= a WC – b
(1)

Where a is the slope and b intercept of El 1.

The TC, i.e., the level of cover in the trigger month below, which predicts DC the following summer, was determined using a regression equation for August for each property to calculate the DC (Eq 2).

TC= DC -b) / a
(2)

Using the exact rounded TC, e.g., 65%, and DC, e.g., 50%, ignores errors in the estimates of the values. In determining if TC or DC occurred in any month, we added a tolerance of 2.5%. This value was chosen because it is half the possible rounding error. For example, if the measured WC was 67% and the TC was ≤ 65%+2.5%, the TC was said to have occurred. Similarly, if the MSC was 51%, and DC was ≤ 50%+2.5%, the TC was said to have occurred.

Years with DC and TC were counted for each property. The 'Prediction of Drought" model (PoD) was said to work when the TC and DC conditions were met. PoD performance was calculated by counting PoD years and dividing by the DC years (Table 1). Errors in the model were assessed as follows: yearly counts of no trigger measured, but DC occurred in summer, and the trigger was measured, but no DC occurred.

Results

The results of the fractional cover time series analysis successfully identified the DC, the TC, and the TC month for each property. The values were different for each property. August had the highest coefficient of determination (R2), with 83% of properties, July 12%, and June 4%. For simplicity, August was chosen as the trigger month for all properties. TC ranged from 35 to 75%, and DC ranged from 25 to 60%. The cover declined, i.e., the difference between TC and DC, 10 to 20%. Properties with low differences were stoney or had tree cover. Properties with large differences were either treeless or sandy country with scattered trees and shrubs.

On average, across the 24 properties, 33% of years between 2002-2022 experienced DC in summer months, while the PoD model predicted DC for 27% of years (Table 1). The primary test was to evaluate if the model could predict TC and DC for a year when DC occurred. To evaluate this test, we divide the years when the PoD model worked (27%) by the DC years (33%). The method correctly predicted 82% of years that recorded DC. The method failed, i.e. no trigger was measured, but DC occurred in six per cent of years; similarly it failed in six percent of years when a trigger occurred, but DC did not.

Table 1. The results for the 22 years, 2002-2022, of the 24 properties in western New South Wales. Results expressed as a percentage of 22 years

	Years when drought cover was recorded (DC) (%)	Prediction of droughts (PoD) (%)	No trigger was measured, but DC occurred next summer (TnDCy) (%)	The trigger was measured, but no DC occurred (TyDCn) (%)
Minimum	23	14	0	0
Maximum	64	64	23	32
Average	**33**	**27**	**6**	**6**

Discussion [Conclusions/Implications]

Remote sensing and modelling are widely used to estimate drought (Mishra and Singh 2011; Vicente-Serrano *et al.* 2020; Fleming-Muñoz *et al.* 2023; Guillory *et al.* 2023). Drought forecasting plays a significant role in risk management and drought preparedness (Mishra and Singh 2011). Landholder discussions have revealed that it is difficult to know when drought is coming because it can be a slow process of change (Van Loon *et al.* 2024). This contributes to the difficulty of recognising the onset of drought and is one reason we have sought to set objective trigger months and cover levels.

This study defines a property-based decision trigger point for when to destock. The aim was to have a month for the decision and a trigger cover level that would indicate that the cover level will likely be lower than that previously measured in drought during summer. The trigger would link to destocking management action to avoid soil erosion. Land managers in western NSW rangelands utilise a range of triggers for destocking, including drought forecasts produced by various agencies, cumulative rainfall, and visually assessing pasture biomass and cover. Some managers have specific months to decide stocking rates based on past experiences and risk determination. The results of this study build on this concept to provide objective property scale metrics.

We calculated the triggers using cover as the metric because cover is closely related to soil erosion. Other drought indices, e.g., rain and soil moisture, are related to vegetation growth and cover but do not describe the cover. Using the cover metric, the analysis found that 32% of years had cover dropping to below DC levels. When PoD is expressed as a percentage of years with DC, the model worked 82% of the time. Increasing the tolerances, currently 2.5%, for TC and DC could improve the PoD model.

Averaged across the 24 properties, DC was measured in 32% of years, and PoD worked in 27% of the 22 years. Of those years when DC was measured, 82% had a predicted TC, and the cover level went to DC levels; that is, the model worked. In this study, destocking too early would have occurred 6% of the time because a trigger was measured, but the cover did not drop to DC levels the following summer. Destocking, in this case, would mean forfeiting production. When discussing the model results with producers in western NSW, one manager said, “You have to own your decision”, and pointed out that this scenario would result in the country getting a rest. The opposite situation of having no trigger and DC occurring the next summer means the model failed to predict the upcoming DC levels, and no management action would be taken. This would result in an increased risk of erosion.

This project demonstrates a trigger method that improves the clarity and transparency of management decisions. The approach can also be applied to paddocks or individual landforms. Cover can be used as an early warning before the onset of drought, which helps maintain cover going into drought.

A tool for guided state and transition model development based on ecological theory

. Bestelmeyer, B.T[1]; Williamson, J.C[1]; and McCord, S.E[1]

*USDA-ARS Jornada Experimental Range, Las Cruces, NM, USA

Key words: ecosystem dynamics; land degradation assessment; monitoring

Abstract

State-and-transition models (STMs) are ideally suited to provide management and restoration guidance as well as site-specific benchmarks for land degradation monitoring and measurement, monitoring, reporting, and verification for ecosystem service markets. STMs, however, have been difficult to produce with sufficient consistency, utility, and accessibility to serve these functions. To address these problems, we developed the State Transition Classifier and State Transition Atlas tools that guide users through the production of STMs featuring 1) guidance for defining land units based on the maximum spatial extent of an STM, 2) menus for attributing each STM component (i.e. states and elements of transition narratives) with standard, logic-based classes, 3) guidance for structuring STM narrative portions in an efficient and consistent way, 4) guidance for inclusion and interpretation of quantitative indicators and benchmarks, and 5) an online storage and display solution (the Atlas). These tools support collaborative development of STMs at a variety of scales and can be adapted to different classification systems used on rangelands globally. The Classifier and Atlas can facilitate a broad understanding of rangeland ecosystem dynamics by developers, users, and the public at large.

Introduction

Evaluation of land degradation supporting land health and sustainable development goals is an ongoing global challenge (Cowie et al. 2018). There is vast heterogeneity in potential ecosystem conditions and their responses to global change drivers. Unrecognized heterogeneity can lead to incorrect assessment of land degradation and counterproductive responses. For example, afforestation of naturally treeless grasslands, based on the assumption that open ecosystems were deforested at some time in the past, is symptomatic of misidentified land potential (Briske et al. 2024). Furthermore, misidentification of ecological constraints to recovery in true instances of ecosystem transition can accelerate, rather than reverse, land degradation. For example, use of fire or physical removal of woody plants to recover historical grassland degradation in some circumstances can trigger increased soil erosion and worsen land degradation (Karban et al. 2022).

State and transition models (STMs) provide a means to organize scientific information about causes and management of ecosystem transitions according to variations in land potential (e.g. via ecoregions or ecological sites). STMs are used globally for evaluating, mapping, and managing ecosystem services

(Eastburn et al. 2017; Han et al. 2022; Jones et al. 2023; Peinetti et al. 2019; Sato and Lindenmayer 2021). By classifying land areas to discrete states based on ecosystem processes, STMs provide mappable benchmarks for land evaluation. STMs can house qualitative and quantitative information about the consequences of state transitions for ecosystem services. Thus, STMs can play central roles in the measurement, monitoring, reporting, and verification of carbon storage and other processes for ecosystem service markets and climate commitments. Furthermore, STMs can guide restoration investments. Restoration successes and failures can be predicted by variation in soil, climate, and the characteristics of existing vegetation states (Brudvig and Catano 2024).

While many STMs have been developed, the unorganized body of models has several critical limitations, including 1) lack of consistency and accuracy, 2) lack of spatial coverage, 3) vague or incorrect application to specific land areas, and, consequently, 4) limited utility for decision making. Systematic development of STMs is a requirement for databasing STM information and helps to create logical consistency and scientific credibility.

We developed two tools, the State Transition Classifier and State Transition Atlas. The Classifier is a web-based tool to develop STMs using a consistent model structure and choice lists for each STM component. The Atlas is a global database for building and storing STMs linked to spatial data and related information for different ecoregions that is useable by the public.

Methods and Tools

The guided STM format, called the State Transition Classifier, was developed from literature review using terminology for STM components including states, triggers, resilience management (actions affecting the ability of triggers to cause a transition), feedbacks reinforcing alternative state after transitions occur, and restoration practices to overcome specific feedbacks (Bestelmeyer et al. 2017; Suding and Hobbs 2009). Each component is associated with a drop-down list of potential categories, also derived from the STM literature. When logically constructed, this format creates an STM "class" or syndrome. Options for descriptive narratives and data tables are also included for most components to provide region-specific details.

Two web applications were developed. The State Transition Classifier (https://webapps.jornada.nmsu.edu/transition-classifier) is accessible to anyone interested in exploring STM development through an interactive interface. This application encourages users to catalog the changes that can occur within an ecosystem of interest. It displays transitions graphically and lets users assign Classifier categories to diagram components using point-and-click features. Once a set of transitions has been created, users are able to connect these transitions to form a complete STM. Classifier attributes are incorporated into STM diagrams and providing a concise visual summary of the mechanisms that lead to (and potentially reverse) ecosystem transitions.

The Classifier is meant to be a temporary repository of ecological information. It is a place where users can think through ideas about STMs in a non-committal way. Transitions created with the tool are saved in an IndexedDB database on the user's device so that users can return to their work at a later time. Aside from exporting STMs from the tool as JSON documents and graphics (Fig. 1), however, users have no way to share the STMs they create with a broader audience.

We developed a second web application to extend the functionality of the Classifier and facilitate more effective information sharing. With the State Transition Atlas, users can create and characterize ecosystem transitions just as with the Classifier application. In addition, the Atlas provides a place where uses can archive STMs indefinitely, map regions where STMs are applicable, and share STMs with a global audience. Users must register with the Atlas project to publish information to the platform. Published STMs can be either public (i.e., accessible to everyone) or private (accessible only to a group of invited users). Users invited to the platform can be assigned read-only, read-write, or administrative access. Whereas the Classifier is a single-page web application served as a static website, the Atlas requires more sophisticated system architecture. It includes a website, server application, and supporting document database. STM documents exported from the Classifier can be imported seamlessly into the Atlas application. The structure of the Atlas enables future integration with monitoring and other key rangeland management datasets (McCord et al. 2023) to support streamlined assessment and management decision making.

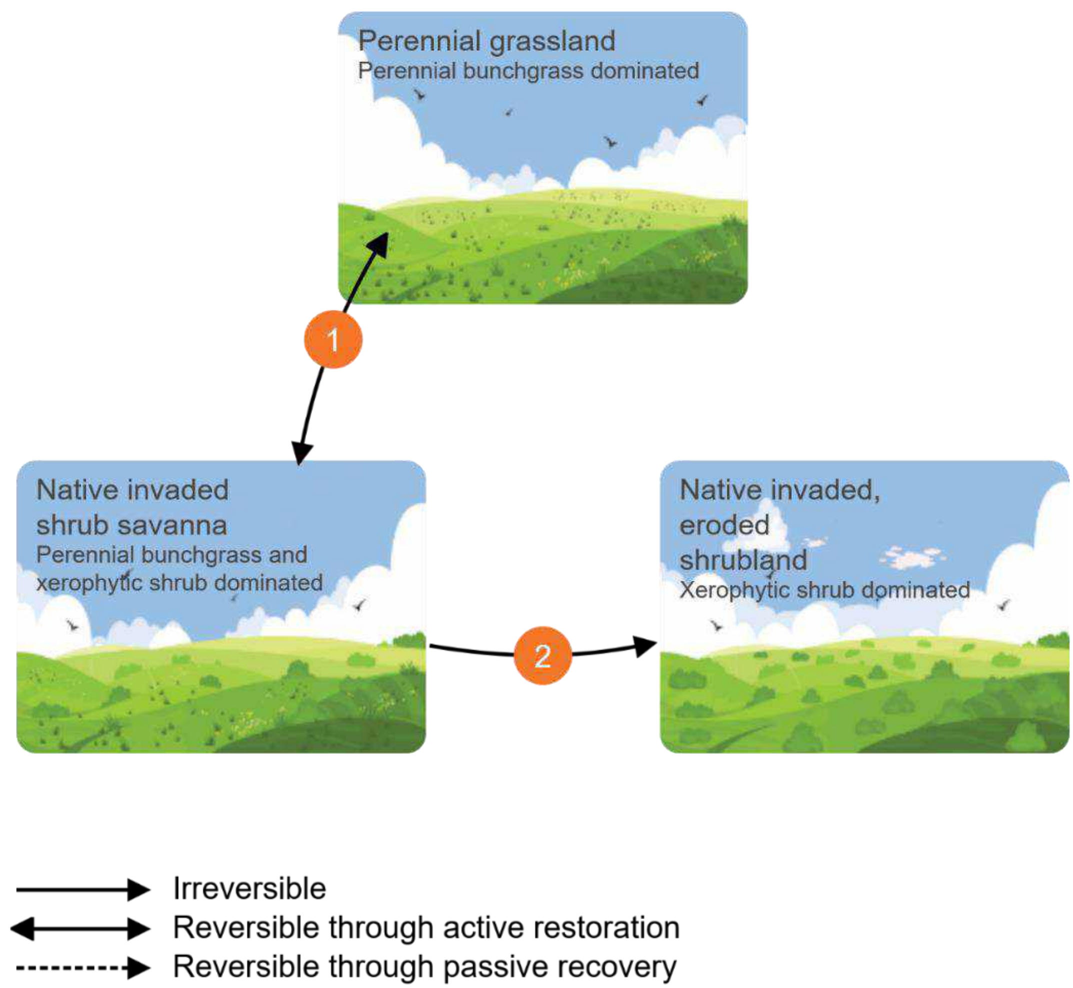

Figure 1. A simplified example of the Ecosystem Transition Sandbox graphical format. State and transition details can be added.

Discussion

The Classifier and Atlas have undergone preliminary testing and refinement and will undoubtedly be refined further. Regarding the Atlas, the governance of a body of STMs that can be produced by multiple users is a challenging problem. Even with the structure provided by these tools, logically inconsistent and conflicting models can be produced by different users. Thus, we are developing a strategy involving the production of global STM "syndromes" based on ecological mechanisms in the scientific literature as a first step for the Atlas, followed by national-scale application of the syndromes and adding details and benchmarks as a second step carried out by vetted, inclusive, collaborative groups. Participatory development of STM information is essential for their practical use in managing communal natural resources (Knapp et al. 2011). Separating development of syndromes as a first step from details and benchmarks as a second step in effect separates arguments about the ecological mechanisms underpinning STMs from values and experiences in local to national land management. This approach, we hope, will simplify the production of STMs and accelerate their use for the science-supported monitoring and evaluation of rangelands. We expect that such revised approaches to STM development will improve the accessibility, consistency, and quality of information to pastoralists and the institutions seeking to promote rangeland resilience.

Mapping depleting aquifers in drylands and the impact on net primary productivity

Gilbert, WQ[1]; Washington-Allen, RA[1]

[1]University of Nevada, Reno.

Key words: Carbon Dynamics; Gravimetry; Groundwater; Remote Sensing

Abstract
The Gravity Recovery and Climate Experiment (GRACE) satellite can measure changes in the height of the water table within 1 cm, unfortunately, GRACE has a horizontal pixel resolution of 40 km X 40 km. We selectively applied a GRACE-based downscaling approach to model the change in the height of groundwater from 2003 to 2017 within distinct groupings of hydrographic basins. We determined that the existence of distinct hydrographic systems at spatial scales smaller than the scale of GRACE pixels does not appear to preclude this downscaling methodology. We then compared this change in the height of the water table over the entire state of Nevada to a net primary productivity (NPP) disturbance map of the frequency of drought on the landscape. We found no significant correlation between disturbance frequency and the modeled change in water table height, implying that aquifer overdraw is not predictive of a reduced ability for the landscape to resist disturbance.

Introduction
Researchers have increasingly turned to NASA's GRACE and GRACE-FO gravimetric missions to address longstanding difficulties in monitoring Earth's groundwater resources. The major limitation of these instruments is the extremely coarse spatial resolution of the data they produce (40-km pixels, Wiese et al, 2016). Numerous research teams have developed methodologies to compensate for this limitation by integrating GRACE data into empirical models alongside finer-resolution climatological and geographic data, that effectively allow for GRACE data to be downscaled to more useful spatial resolutions.

However, many of the most widely-cited GRACE downscaling studies have trained, applied, and validated their empirical models over relatively straightforward topographies (Miro and Famiglietti 2018, Chen et al 2019). There is a need for additional work to refine our understanding of what spatial scales GRACE downscaling methods can be applied and what landscape factors affect the validity of these methods.

The goals of this experiment were:

1. Determine whether GRACE downscaling methods are valid when the study area contains hydrographic basins where no in-situ training or validation method is available.

2. Determine whether trends in downscaled GRACE data correlate with observed anomalies in landscape productivity.

Methods

The study area for this experimentation was the U.S. state of Nevada, chosen because it is 98% Dryland, and its complex basin-and-range topography maximizes the density of distinct hydrographic systems within the footprint of each GRACE pixel. The GRACE downscaling method we utilized for this experiment was a linear regression from least squares (Vishwakarma et al 2021), which was chosen because this experiment was a sensitivity analysis more so than an attempt to maximize model accuracy. The modeled variable was the flux of the height of the water table, with the interannual period resetting in March rather than January due to the greater availability of in-situ well measurements. March is also the beginning of the growing season for Nevada's primary dryland crops.

The in-situ data for this experiment were compiled from records maintained by the Nevada Division of Water Resources (NDWR 2024). The majority of these records were drawn from private agricultural and industrial users, with great variation in the quality and consistency of record-keeping. Because of the inconsistencies within these data, we applied GRACE downscaling to the overall trend of the water table from 2003 to 2017 rather than to an interannual time series. Applying GRACE downscaling methods at decadal rather than interannual timescales has some precedent in the literature (Scanlon et al, 2018).

We addressed our first research goal by utilizing two different methods of organizing training/validation data from in-situ records. We also leveraged the set of hydrographic basins delineated by past surveys (USGS, 1971). To produce our first dataset, we simply withheld 20% of the available site records for validation purposes, and otherwise used the available training data irrespective of location or site type. We refer to this as **the basin-inclusive method**.

To produce our second dataset, we chose a subset of hydrographic basins from within the study area and used in-situ records from these as training data. We then chose a second subset of hydrographic basins from within the study area to use as validation data. These basins were non-contiguous, meaning that the validation data were both spatially and hydrographically discontinuous from the training data. We refer to this as **the basin-exclusive method**.

The two methods cannot be directly compared because of the differing distribution and amount of training and validation data available in each case. However, we reasoned that if the second training/validation approach produces a respectable accuracy, we may have some confidence that the aquitards between hydrographic basin do not invalidate GRACE downscaling approaches applied over areas that contain multiple distinct hydrographic systems.

We addressed our second research goal by applying our downscaling approach to the entire State of Nevada and then compared this to a raster representation of the frequency of drought disturbance on vegetation in the landscape. This raster represented drought "disturbances" as events where the annual net primary productivity NPP (Robinson et al, 2019) decreased 20% or more relative to the time-series mean. We reasoned that since most of Nevada's waterways are groundwater-dependent, consistent aquifer overdraw may be reflected in the landscape's resilience to disturbance. We tested this hypothesis by testing for spatial correlation between this disturbance frequency and the modeled change in water table height.

Results

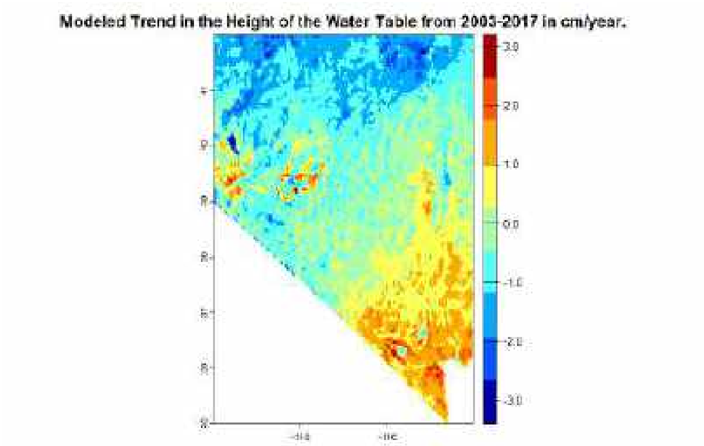

Figure 1: The state of Nevada model output based on the basin-inclusive training/validation dataset. The set of predictor variables include the flux in precipitation (mm), the flux in mean annual temperature (*C), the soil water content at field capacity at 200 cm depth, the soil bulk density (kg/m^3) at 200 cm depth, and elevation (m). These variables were retrieved via Google Earth Engine (Earth Engine Data Catalog, 2024). The target resolution for this method was the 4km resolution of the PRISM precipitation dataset (Daly et al, 2008). This model had a RMSE of 2.8 cm/year and a normalized RMSE of 0.15.

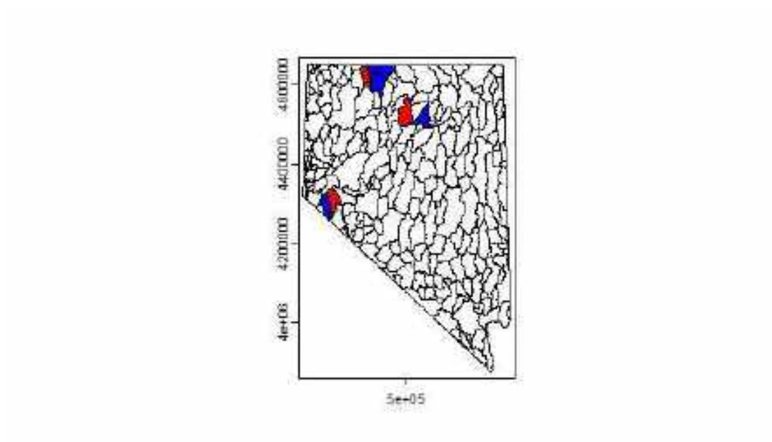

Figure 2: The basins chosen for the first, basin-selective training/validation dataset. Basins in blue contained points used for training, basins in red contained points used for validation. The model was trained using the basin-exclusive training/validation dataset and had a RMSE of 1.8 cm/year and a normalized RMSE of 0.15, indicating that the model is somewhat less reliable than the one produced using the basin-inclusive data.

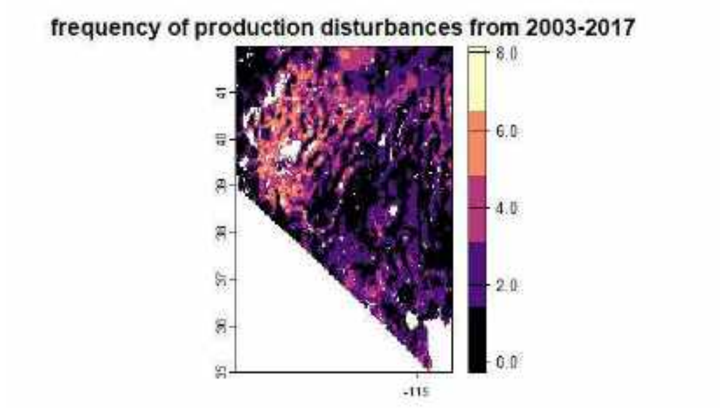

Figure 3: The drought disturbance net primary productivity (NPP) frequency raster was used to test whether there was an observable relationship between the GRACE modeled change in the water table height and the resilience of groundwater-dependent ecosystems. We observed no significant spatial correlation between these variables ($p = 0.17$).

Discussion

These experiments revealed a considerable need for further investigation. The basin-exclusion method for investigating the effects of aquitards on the downscaling methodology shows promise, but could be refined by more carefully curating the excluded basins to control for underlying geology and dominant land-use type.

The lack of correlation between groundwater levels and disturbance frequency could have several causes, and likewise indicates a need for more refined investigation. This could indicate that the groundwater model performs unreliably in areas between or far away from training/validation points, or the correlation could be thrown off by the behavior of agricultural water users, who account for a majority of groundwater usage and may be maintaining artificial "islands" of stable landscape production at the cost of aquifer overdraw. Controlling for land use in future iterations of this experiment should allow us to isolate which of these explanations is more likely.

Abstract

Industry-oriented research innovations during the past decades have significantly contributed to the productivity, profitability and sustainability of pastoral industries. Key examples of these innovation efforts include (1) sensor, IoT and machine learning technologies facilitating automation of data collection, data integration and model simulation towards digital decision tools for farmers, and (2) simulating the consequences of changed environment and/or management practices on rangeland and pastoral systems through integrating biological, physical and digital properties and processes across leaf, whole-plant and paddock levels. However, there are fundamental physiological processes which are not well reproduced by models, partly due to the challenge of bridging the advancement of cross-disciplinary knowledge. This paper reviewed recent experiment-modelling-integration efforts towards the accurate model representation on light-response of photosynthesis, in particular: the performances of two models – the most widely used non-rectangular hyperbolic model (NH model) and a more recently developed mechanistic and nonasymptotic model (Ye model) – in reproducing plant photosynthetic light response across light-limited, light-saturated and photoinhibitory light intensity levels. The accuracy of Ye model, and its consistency of model framework, in reproducing the light responses of concurrent photosynthetic functions (i.e., photosynthesis, electron transport rate, stomatal conductance and water use efficiency), make it ideal to be adopted by the current and future experiment-modelling-integration efforts on global rangeland, pastoral and/or broadacre production systems.

Introduction

Plants growing in natural or semi-natural systems experience fluctuating light environments over time scales extending from seconds to hours, largely due to cloud movements and self-shading. Accurate characterization of light-response curve of photosynthesis at leaf scale is fundamental for quantifying crop light relations at whole-plant and community scales. An accurate model should be robust in reproducing light-response curve of photosynthesis (PN–I curve) over light-limited, light-saturated and photoinhibitory I levels, and ideally returning key quantitative traits defining the curves, including initial slope of increase (α), dark respiration rate (RD), the maximum net photosynthetic rate (PNmax) and the corresponding saturation intensity (Isat).

A few models have been developed to characterize the light response of photosynthesis of higher plants, including biochemical models, rectangular and non-rectangular hyperbolic models, negative exponential equations, and nonasymptotic function models. The non-rectangular hyperbolic model (NH model) is the most widely used (Holley, 2022).

The FvCB model (Farquhar, von Caemmerer and Berry, 1980) has been widely used to characterize leaf gas exchange. In the FvCB model, the NH model is a sub-model to characterize the light response of electron transport rate (*ETR*–*I* curve, using the same function as the above P_N–I model) besides estimating the maximum electron transport rate (ETR_{max}) (Farquhar & Wong, 1984). Unavoidably, due to its asymptotic function, the NH model overestimates ETR_{max} when the model is fitted against observations. Besides, since early years, the NH model has been reported on its failure in reproducing the *ETR*–*I* curve at photo-inhibitory *I* levels (Ögren & Evans, 1993).

This paper reviewed recent studies comparing the performances of two different models (NH model and Ye model) in reproducing the light response curves of *ETR and* P_N.

Methods

NH model on the light response of photosynthesis and electron transport rate

The NH model describes the P_N–I function as below (Thornley 1976, Ögren and Evans 1993, Thornley 1998):

$$P_N = \frac{\alpha I + P_{Nmax} - \sqrt{(\alpha I + P_{Nmax})^2 - 4\theta\alpha I P_{Nmax}}}{2\theta} - R_D \quad (1)$$

where P_N is net photosynthetic rate, P_{Nmax} is the maximum net photosynthetic rate, α is the initial slope of curve, *I* is light intensity, θ is the curve convexity (dimensionless), and R_D is the dark respiration rate.

ue to its asymptotic function, the NH model can only indefinitely approach to, but never reach, a maximum net photosynthetic rate (and thus cannot return the corresponding saturation *I*). This means that (1) the P_{Nmax} generated by fitting the NH model will be unavoidably overestimated, and (2) the NH model cannot reproduce the curve section at and after the saturation *I* (where photoinhibition occurs).

The non-rectangular hyperbolic model has been mainly used to fit the *ETR*–*I* curves of plants, and it has been a sub-model in the FvCB model when irradiance is below the saturation level. In the NH model, the dependence of *ETR* on *I* can be expressed as follows:

$$ETR = \frac{\alpha' \times I + ETR_{max} - \sqrt{(\alpha' \times I + ETR_{max})^2 - 4\theta \times \alpha' \times I \times ETR_{max}}}{2\theta} \quad (2)$$

where α' is defined as the initial slope of the *ETR*–*I* curve, θ is a degree of curvature, and ETR_{max} is the maximum *ETR*. Because the first derivative of Eqn. 2 is always greater than zero, we cannot use Eqn. 2 to estimate the saturation *I*.

Ye model on the light response of photosynthesis and electron transport rate

The Ye model describes the P_N–I function as below (Ye 2007; Ye *et al*. 2013):

$$P_{\mathrm{N}} = \alpha \frac{1-\beta I}{1+\gamma I} I - R_{\mathrm{D}} \quad (3)$$

where α is the initial slope of P_N–I curve, R_D is the dark respiratory rate, and β and γ are the photoinhibition coefficient and saturation coefficient, respectively (Ye *et al*. 2013). Due to its nonasymptotic function, Ye model can calculate the actual P_{Nmax} and the actual corresponding saturation I (I_{sat}).

According to Ye *et al*. (2013), the photosynthetic electron transport rate (*ETR*) via PSII can be described as:

$$ETR = \alpha_e \frac{1-\beta_e I}{1+\gamma_e I} I \quad (4)$$

Since Eqns. 3 and 4 are of the non-asymptotic function, they have the first derivative. When the first derivative equals to zero, the maximum net photosynthetic rate (P_{Nmax}), the maximum electron transport rate (ETR_{max}) and their corresponding saturation intensities (I_{sat}) can be calculated.

Results

Ye model can accurately characterize the *ETR*–*I* curves (Figure 1) for various C_3 and C_4 species across light-limited, light-saturated and photoinhibitory *I* levels. Its robustness and accuracy in reproducing P_N–I curves are consistent at different temperature and CO_2 concentration levels (Figure 2).

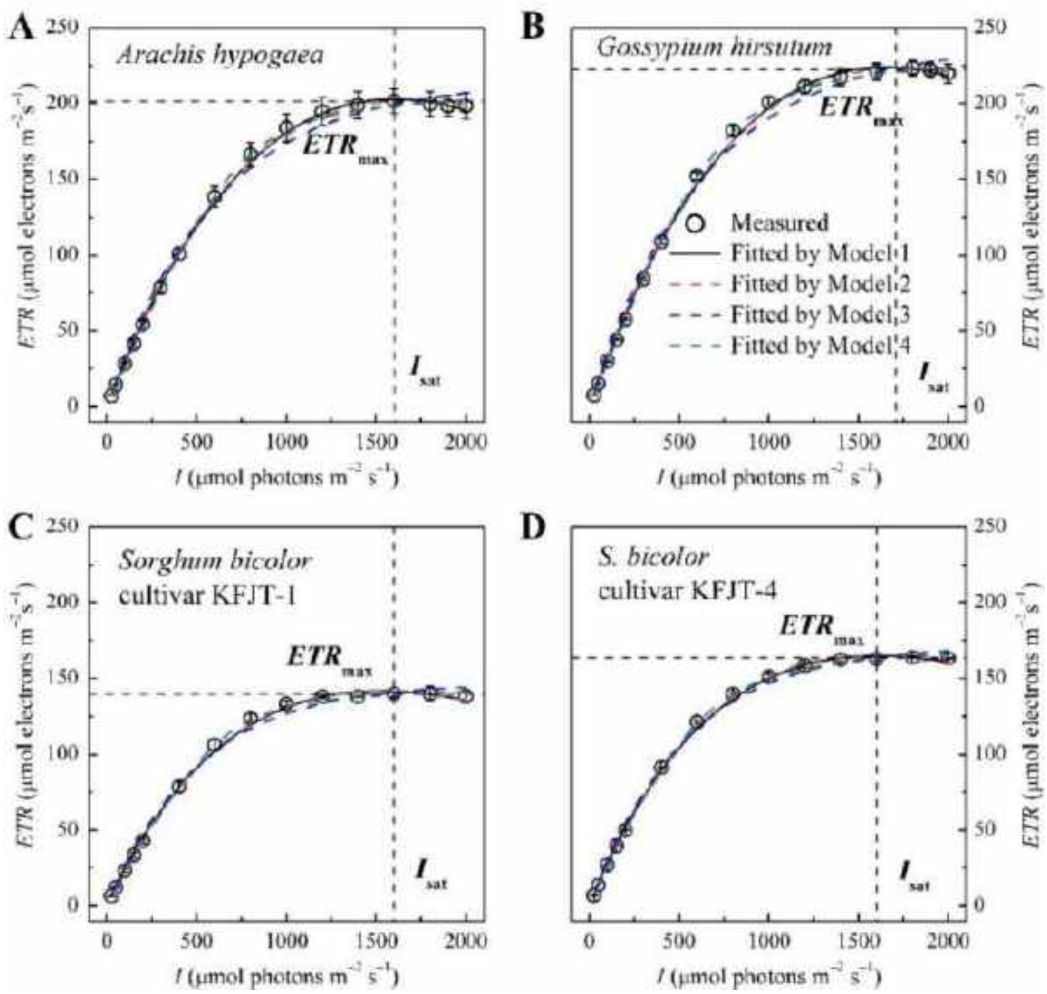

Figure 1. Light-response curves of the electron transport rate (*ETR–I*) for *Arachis hypogaea* (**A**), *Gossypium hirsutum* (**B**), *Sorghum bicolor* cultivar KFJT-1 (**C**) and *S. bicolor* cultivar KFJT-4 (**D**). The curves were simulated by Model 1 (Ye model), Model 2 (negative exponential function), Model 3 (exponential function), and Model 4 (non-rectangular hyperbolic model). A black horizontal dashed line represents the observed value of ETR_{max}, and a black vertical dashed line represents the observed value of I_{sat}. Data is sourced from Yang et al. (2025).

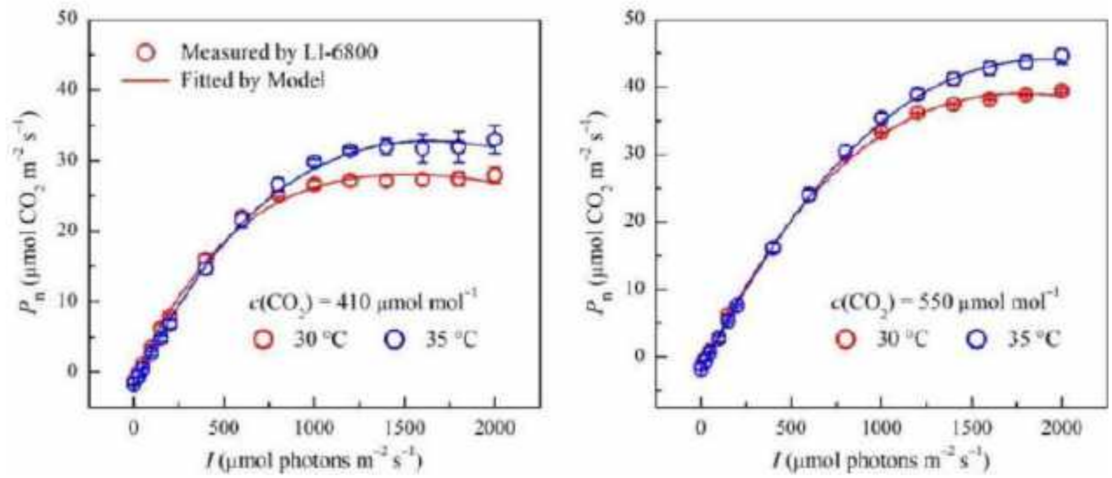

Figure 2. Photosynthetic light response curves fitted by the Ye model for leaves of sweet sorghum under different temperature and atmospheric CO_2 levels (410 and 550 mmol mol^{-1}) and air temperatures (30 and 35°C). Data is sourced from Yang et al. (2024).

Discussion and conclusion

Using an experiment-modelling-integration approach, Ye et al (2021) highlighted that Ye model can well address the limitations of NH model such as (1) underestimation of dark respiration rate (2) overestimation of the maximum net photosynthetic rate and (3) failure in reproducing the photoinhibitory response over both low *I* levels (i.e., 0–50 µmol m^{-2} s^{-1}) and photoinhibitory *I* levels (i.e., when *I* surpassed the cultivar-specific saturation light intensity). Using a consistent model framework as the P_N–I model, Ye et al (2020) reported Ye model can accurately reproduce the *ETR–I* curve, while the NH model significantly overestimated the maximum electron flow for carboxylation but not that for oxygenation, highlighting the reason underlying why the NH model would overestimate P_{Nmax} and ETR_{max}.

This paper reviewed recent research efforts using the experiment-modelling-integration approach to address the long-standing limitations of asymptotic models, and highlighted the long-lasting limitations of the most widely used non-rectangular hyperbolic model (NH model) such as (1) NH model led to underestimation of dark respiration while overestimation of the maximum net photosynthetic rate, and (2) NH model failed in reproducing the photoinhibitory response when light intensity surpassed the species-specific saturation intensity. The more recently developed mechanistic model (Ye model), attributed with its nonasymptotic function, addressed the above limitations of NH model extremely well.

Accounting for carbon stock change in Australia's rangelands – a hybrid approach using remote sensing and empirical modelling

Rosauer, DF[1]; Pasut, C[2]; England, JR[3]; Forrester, DI[1]; Piper, M[1]; Caccetta, P[4]; Chia, J[4]; Levick, S[5]; Paul, KI[1]

Key words: greenhouse accounts; remote sensing; biomass

Abstract

Australia's rangelands are under varying types of land-use and management, including cattle grazing, Indigenous fire management, and activities encouraging regeneration of native vegetation to restore biomass and earn carbon credits. Despite the typically sparse vegetation, the vast area of the rangelands (almost 6 million km^2) is a substantial stock of land sector carbon. Changes in these stocks, whether due to management or wet - dry climate fluctuation, are thus a major contributor to Australia's overall carbon fluxes. Improving estimates of greenhouse emissions and sinks in the rangelands is thus essential to fulfil Australia's climate change treaty obligations, and also to account for land management effects in carbon credit schemes.

Here we present a new approach to account for land-sector carbon, targeted principally at the rangelands. Recent work has quantified the relationship between canopy cover and above-ground biomass (AGB) across Australia's rangelands. We extend the widely-used Full Carbon Accounting Model (FullCAM), using a time-series of remotely-sensed woody cover to estimate changes in AGB through time. This time series is integrated with the FullCAM model, to combine observed changes in woody cover with the effects of fire, litterfall, decay and soil respiration, to account for greenhouse emissions and sinks through time.

We introduce and demonstrate this approach for rangeland areas. Once this approach, informed by satellite monitoring of woody cover, is scaled up, it is anticipated that FullCAM will reduce model uncertainty by integrating empirical biomass estimates with a process-based modelling framework.

Introduction

Rangelands occupy approximately 40% of the global surface and provide critical ecosystem services, such as forage for livestock, soil stabilization, biodiversity habitat and climate change mitigation. Given their vast extent, even minor changes in carbon stocks can have significant impacts on the global and national carbon budgets. Woody biomass is a key component of the carbon cycle in these environments, with increasing woody vegetation associated with benefits including enhanced carbon sequestration.

Estimating and monitoring woody biomass in Australia's rangelands is challenging due to diverse vegetation types, complex disturbance regimes (grazing, fire, drought) and associated high spatial and temporal variability. Australia's National Greenhouse Accounts (Australian Government, 2024) use the Full Carbon Accounting Model (FullCAM; Richards and Evans, 2004; Forrester et al., 2024), to monitor and report carbon emissions and sequestration from the land sector. The FullCAM framework estimates accumulation of tree biomass using an empirical growth relationship known as the Tree Yield Formula, with parameters including maximum above-ground biomass (AGB), age of maximum growth, and importantly, stand age. This approach to estimating biomass, and thus carbon, depends on the date from which a given stand began to grow. In rangeland systems where vegetation dynamics may be dominated by diffuse cycles of biomass increase and decrease in response to factors such as climate, grazing and low intensity fire, this approach has limitations.

Canopy cover is strongly correlated with AGB, and remote sensing (including Landsat and Sentinel time series) has been broadly adopted to map vegetation cover, including for aiding the estimation of AGB at large spatial scales (Allred et al., 2021; Jones et al., 2021; Kearney et al., 2022). Modelling AGB directly from time-series estimates of canopy cover may provide an alternative to generalized growth models to better estimate AGB change, and thus carbon flux, in sparse and diverse vegetation, such as Australian rangelands.

This study presents a novel prototype, a variation of the FullCAM model that combines a process-based model of vegetation carbon cycling, with remote-sensed observation of vegetation change, to improve estimation of carbon stocks and flows in the rangelands. By integrating dynamic carbon cycle processes with satellite-derived observations of vegetation cover, this model aims to capture the spatial and temporal variability in rangelands, offering a tool more applicable for carbon accounting and vegetation carbon sequestration projects in these more arid areas. In this paper, we outline the integrated workflow and share the preliminary results.

Methods

We mapped carbon stock for woody vegetation in a rangeland area, through a process with three main stages. The first, a satellite derived time-series of the proportion of woody cover tracked changes in vegetation extent and density. Second, AGB was inferred at each location through time. The ABG was based on woody cover and vegetation structure relationships, previously calibrated over an extensive program of fieldwork. Third, the inferred AGB was incorporated into a model adapted from the Full Carbon Accounting Model (FullCAM; Forrester et al., 2024; Richards and Brack, 2004) alongside other carbon cycling processes such as litterfall and decay, to simulate movement between carbon pools, and overall carbon stock change in the woody component of rangeland environments. These steps are now described in more detail.

Remote-sensed woody cover

The FullCAM framework estimates spatial and temporal regeneration of AGB using a stand-age based empirical growth relationship (Tree Yield Formula, TYF; Paul & Roxburgh, 2020). In rangeland systems where vegetation dynamics are typically dominated by more diffuse cycles of increasing and decreasing biomass in response to factors such as climate, grazing and low intensity fire, this approach has limitations.

The current standard for estimating fluxes of greenhouse gasses related to vegetation change in Australia's Greenhouse Accounts (DCCEEW, 2024) is the national forest and sparse woody vegetation data (Furby, 2002; DCCEEW, 2023) which uses Landsat satellite data for the period since 1988 to derive an annual classification of Australia's vegetation cover into 3 categories: woody vegetation (forest, >= 20% tree cover), sparse woody vegetation (5% to <20% cover), and non-woody (<5% cover). This dataset tracks changes through time in the extent of forest, particularly for well-defined changes such as clearing of forest, and the establishment of new or restored forest areas, but is not sensitive to changes in cover within those categories. Thus its use in carbon accounting relies on growth and recovery functions to simulate biomass accumulation through time (Forrester et al., 2024), calibrated to empirical datasets.

In this study we trialled a new remote sensing approach to capture the full range of variation in woody cover, enabling direct observation of changes in woody cover to be translated into time-specific estimates of above-ground biomass and carbon pools. This approach to estimate cover (Chia et al., 2024) partitions Landsat multi-spectral reflectance into multi-variate proportions (MVP) for four ground-cover classes: woody, dry grasses, green grasses and soil (bare) based on spectral unmixing algorithms described by Berman et al. (in prep). The timing of images is selected to provide a yearly value representing permanent woody cover, typically during the dry season (July for northern and northeastern Australia, and January for central and southern Australia). The time series covers the period 1988 to 2022 at 0.00025 degree (~25 m) resolution. Annual cover values were interpolated to monthly by assuming linear change between observed values and extrapolated to use the earliest observed value for years prior to 1988.

Cover to biomass

Our 'cover-to-biomass' model is based on the quantitative relationship between canopy cover and AGB which Pasut et al. (in press) derived from an extensive dataset of field measurements. These measurements, collected from 431 field sites across the Australian rangelands, included live AGB and standing dead AGB, with sites stratified to represent the region's variability. The resulting log-linear relationship between woody cover proportion and above-ground biomass, is expressed here as:

$$AGB = e^{b\,ln(C)} * B_f \qquad \text{Eq.1}$$

where AGB is above-ground biomass; b is the scaling factor for cover; C is the percentage of woody cover; and B_f is the Baskerville correction factor.

The model was calibrated for three broad vegetation structural types, *shrub-dominant*, *Acacia-dominant* and *tree-dominant*, with values of b and B_f for each vegetation structural type.

Integrated land carbon model

We adapted the FullCAM model framework to estimate AGB using remotely sensed cover data. For detail on the FullCAM framework see Forrester et al. (2024). The existing FullCAM uses a growth curve in which the annual increment in living tree biomass depends on parameters including tree-stand age (dated to detection of new forest cover) and time since disturbance. The cover-to-biomass model however, ties changes in AGB to continuous vegetation change, estimating AGB from annual observations of cover, rather than a growth curve.

Other model components follow the existing FullCAM approach, where the vegetation class at each location is defined from the National Vegetation Information System (NVIS) Major Vegetation Groups. AGB is allocated among living carbon pools (stem, bark, branches, leaves) using FullCAM proportions for allocation of live biomass which are specific to each vegetation class, with below-ground tree biomass similarly assigned to fine and coarse root carbon pools in proportion to AGB. Turnover (such as litterfall of leaves and bark to debris) and decomposition of debris are predicted using an exponential decay model that quantifies the rate at which carbon moves between pools. Fire events were not directly simulated in this study, although the effects of fire on loss of woody biomass and its subsequent recovery, are included where they affect observed woody cover. Non-CO_2 greenhouse gasses are not included at this stage.

Flux of carbon between land and atmosphere occurs in this model in two ways. First, during the decay of non-living biomass, a proportion of the carbon is released as CO_2, while the rest of the lost carbon moves to another pool, for example, soil carbon. Second, changes in site carbon mass, primarily due to changes in AGB indicated by the cover-to-biomass function, are treated as direct carbon removals from, or emissions to, the atmosphere, corresponding to increases or decreases in AGB.

In summary, the prototype cover-to-biomass model in this study is a hybrid, combining process-based modelling of carbon transitions / transformation between pools, with an observation-driven component where changes in biomass at each pixel are directly linked to satellite-detected variations in woody cover.

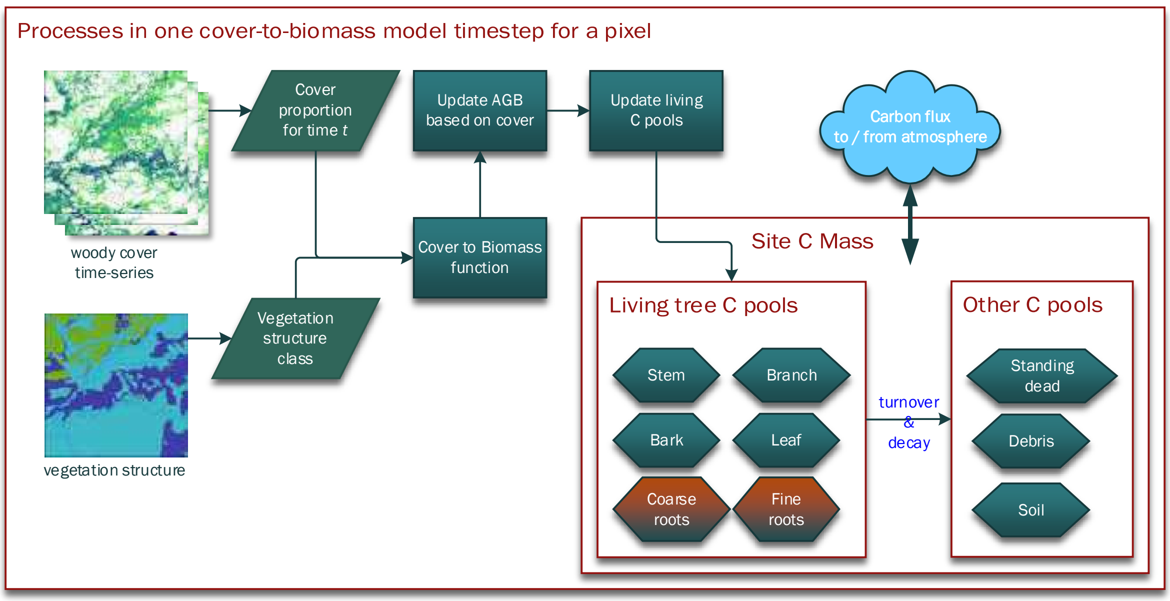

Figure 1. Main processes in the cover-to-biomass model per time-step, for one pixel. Vegetation structure and remote-sensed woody cover percentage for each timestep inform the cover-to-biomass function to update living biomass pools. Turnover and decay processes then populate the debris and soil carbon pools. Atmospheric carbon flux is inferred from changes to site carbon mass.

Results

Results from running the prototype model for an area of 6 million ha (96 million pixels at 25 m resolution) in inland northern New South Wales and southern Queensland, returned values for aboveground living tree C mass ranging from 0 to 79 t C ha^{-1}, and for total stand C mass ranging from 22 to 170 t C ha^{-1}. As expected, results were strongly reflective of local topography and drainage as important drivers of C density, and of patterns of agricultural land-use. Figure 2 shows in detail the estimates of woody cover and of carbon pools for an area along the Barwon River east of Bourke, NSW for the year 2020.

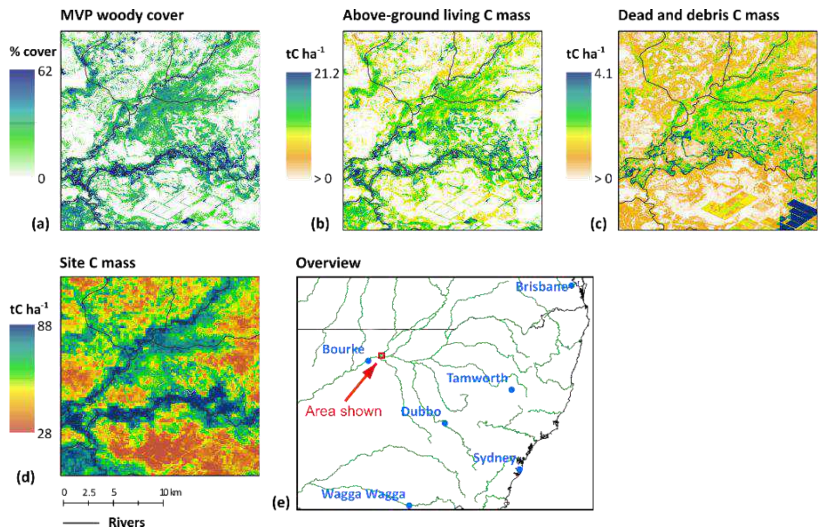

Figure 2. Example model outputs for 2020 along the Barwon River east of Bourke, New South Wales at 25 m resolution, showing a) % of woody cover from the multivariate proportion (MVP) model; b) carbon in aboveground tree biomass; c) carbon in debris and standing dead trees; d) total C mass, including above and belowground tree components, standing dead, debris and soil organic carbon; and e) overview map. The effects of floodplains on biomass are clear, as is irrigated agriculture near the south end of the area.

Discussion

The method and results presented here illustrate the potential of a new approach to estimating land sector C stocks, and subsequently emissions and sinks, in rangeland environments where methods based on stand-level, growth curves may not reflect typical growth trajectories. They introduce an approach based on observed changes in woody cover through time, combined with modelled turnover and decay, which with further development, aims to improve to C accounting across Australia's vast rangelands. A comprehensive accounting approach will also need to include emissions of non-CO_2 greenhouse gasses, especially due to fires, to manage inter-annual variability in cover inferred from remote-sensed cover, and to demonstrate model performance across diverse rangeland environments in comparison to currently used approaches.

Assessment and mapping of rangeland health in East Africa and globally

Vågen, T-G[1]; Robinson, NP[1]; Bargues-Tobella, A[2,3]; Winoweicki, LA[1]

[1] CIFOR-ICRAF, Nairobi, Kenya; 2 SLU, Umeå, Sweden; 3 University of Llieda, Llieda, Spain

Abstract

Rangelands across eastern Africa are in need of urgent interventions to restore rangeland health and build resilience to climate change. Drylands cover nearly half of the global land surface and harbor high biodiversity, yet they remain understudied and undervalued. The compounding effects of climate change and land degradation currently represent a major threat to drylands in general, and rangelands in particular. There are substantial gaps in the evidence base for land restoration with a significant bias towards the Global North and forest ecosystems. This research aims to address key gaps in East Africa around (1) the role of restoration interventions that consider and manage plant-soil-water feedbacks in accelerating the recovery of key ecosystem functions and related ecosystem services, (2) the link between above-ground and below-ground interactions, including biodiversity and (3) how such interventions can be scaled to improve restoration outcomes. The project builds on long-term and robust data collected in the field across a range of rangeland systems in East Africa using the Land Degradation Surveillance Framework (LDSF). We systematically assessed the impact of woody and non-woody vegetation (species, structure, cover, above-ground biomass, diversity), soil inherent properties (soil texture, pH), and land management (grazing and browsing intensity) on ecosystem functioning and the delivery of key ecosystem services, including erosion control, water regulation (soil infiltration capacity), and carbon storage, We present grass, forb and woody species diversity in 11 – 100 km^2 LDSF sites across East Africa, as well as maps of soil organic carbon, soil erosion and herbaceous cover. We will present the use citizen science to enhance the participation of local communities, and in particular women and youth, increasing transparency and inclusion in the various phases of rangeland restoration. These methods can be applied globally and fill key knowledge gaps around rangeland health and the impact of inventions on the ground.

Introduction

Rangelands are vital systems, covering 40-50% of the earth's terrestrial surface, providing essential goods and services such as livestock forage, biodiversity habitats, and carbon sequestration (Sala et al., 2017). In East Africa, these landscapes support pastoral livelihoods, harbour high biodiversity, and play critical roles in regulating regional and global climate systems (Little, 1996; Mgalula et al., 2021). However, they are currently under threat from a combination of pressures, including climate change, unsustainable land management, and socioeconomic factors (Otieno & Kinyamario, 2018). A systematic study of soil erosion prevalence, using the LDSF database, highlighted that drylands were more susceptible, including the vegetation classes of bushland and shrubland. (Vågen and Winowiecki, 2019). This degradation, evidenced by reduced productivity, soil erosion, and decreased biodiversity, demands targeted restoration interventions that are locally relevant, scalable, and informed by robust data. Restoration interventions require both a focus on vegetation recovery, but an understanding of complex plant-soil-water interactions, ground-truthing data, and participatory approaches with local communities. Yet, despite their importance, substantial knowledge gaps around effective, locally applicable and scalable restoration practices in rangelands systems (Boyd & Svejcar, 2009). A pressing need is to develop integrated protocols and tools that capture on-the-ground conditions, produce practical insights, and support locally relevant restoration efforts at meaningful spatial scales.

Our work integrates field data from the Land Degradation Surveillance Framework (LDSF)—a robust field data collection protocol designed for systematic, repeatable environmental assessments of soil health, rangeland health, land degradation and vegetation diversity (Vågen and Winowiecki, 2023; Vågen et al., 2012)—with spatial modelling tools and a citizen science data collection platform. By combining rigorous plot-based data, geospatial remote-sensing analyses, and community-led monitoring through mobile apps, this approach aims to fill critical knowledge gaps and enhance the evidence base for rangeland restoration interventions. We focus on East Africa as a case study region, reviewing both the protocol and the emerging results, and discuss how these methods can scale to inform rangeland restoration interventions more broadly, and be integrated into monitoring, evaluation and adaptive management frameworks.

Methods

The LDSF is a comprehensive field data collection protocol for assessing soil and land health (Vågen and Winowiecki, 2023). It provides guidance and methods for designing and implementing robust sampling strategies across broad, heterogenous landscapes along with tools to sample vegetation dynamics (cover, structure, and function), key soil physical properties, evidence of soil degradation, and historic land use change. The LDSF includes a specific rangeland module tailored to rangeland systems and employs accessible, practical, and affordable methodologies that can be implemented in remote areas with limited technical resources. Data collected through the LDSF support a rangeland health and indicator framework, enabling assessments of soil organic carbon stocks, soil infiltration, soil erosion, vegetation cover and density, species composition and diversity, and overall land degradation status and risk.

The nested, randomized sampling design of the LDSF framework facilitates the evaluation of the indicators at multiple scales, capturing both within- and between-site variability. Moreover, the LDSF integrates effectively with earth observation (EO) data, allowing assessments to span broader spatio-temporal scales. By combining field-derived indicators with medium-resolution (10 – 30m) EO data from Landsat and Sentinel, and applying advanced machine learning modelling pipelines, we can predict indicators of rangeland condition across landscapes at 10 – 30m spatial resolution and through time. This approach supports the development of historic baselines and the evaluation of areas lacking extensive field data availability. In this study we present results from 11 LDSF sites, eight in Kenya, one in eastern Rwanda and two in northern Tanzania, with 1760-1000-m^2 sampling plots. In each plot, there were four subplots each of 100m2, where erosion was scored, tree and shrubs were identified and measured and soil samples were collected. In addition, across each plot, two-15m transects are laid (N-S, E-W) where perennial and annual grasses, forbs and woody vegetation under 1 m tall are assessed.

Integrating field with EO products also improves long-term monitoring of restoration and degradation trends. To enhance the assessment of management and restorations interventions we incorporate a citizen science smart-phone application—The Regreening App (*The Regreening Africa App User Guidelines*, 2022)—which includes a rangeland module. This tool enables smallholder ranchers and land managers, to record the timing, location, and nature of specific interventions. By merging this localized, site-specific information with medium-resolution predictions of rangeland condition indicators, we can produce more robust and context-relevant assessments and evaluations of rangeland restoration initiatives.

Results

As shown for the sites surveyed as part of the GCF-Twende project in Figure 1, they covered a strong gradient in terms of SOC and land degradation status, the latter expressed here as soil erosion prevalence. Sites in the northern parts of the study area are generally lower in SOC (median <5 g/kg) and have higher soil erosion prevalence than sites in southern Kenya, although there are relatively high levels of degradation in all sites. The sites also represented a wide range of management types, including private conservancies, private pastoral land, and communal pastoral land. Species diversity of annual and perennial grasses varied strongly between sites, as well as the types of species present. For example, Mbalambala had very few grass species present and a high proportion of bare ground, as well as presence of invasive species such as *Prosopis juliflora*. In contrast, Mbirikani had higher species diversity and no invasive species were observed. Results from the surveys in northern Tanzania show high levels of bush encroachment in some districts, as well as high rates of conversion of rangelands into agriculture. In West Pokot there has been a transition from communal pastoral systems to private land tenure over the last three decades, resulting in higher levels of fragmentation and hence variability in terms of land use was also high in the Chepareria site.

Discussion [Conclusions/Implications]

Despite their immense ecological, economic, and cultural significance, rangeland systems remain challenging to monitor and assess due to their inherent spatio-temporal variability. This complexity has often hindered the development of robust, scalable frameworks for evaluating rangeland health, restoration progress, and management effectiveness. By integrating standardized field protocols, remote sensing data, participatory approaches, and advanced modeling techniques, our work contributes to overcoming these longstanding barriers. The approaches outlined here help establish reliable pipelines for data collection, analysis, and interpretation, ensuring that locally relevant interventions can be scaled to broader landscapes. Ultimately, this convergence of methods and tools provides a critical foundation for enhancing adaptive management practices, improving restoration outcomes, and ensuring that rangeland systems continue to sustain both livelihoods and ecosystems well into the future.

Mapping the condition of Queensland's grazing lands

Beutel, TS[1]; Graz, FP[1]; Trevithick, R[2] and Hassett, R [1]

[1] Department of Primary Industries, Rockhampton, Queensland; [2] Department of Environment, Tourism, Science and Innovation, Brisbane, Queensland.

Key words: land condition; LCAT; ABCD framework.

Abstract
Grazing land condition is the ability of grazing land to convert rainfall into useful forage and is determined by changes in pasture, soil, and woodland condition. The Grazing Land Management framework defines four condition classes (A, B, C or D), indicating maintenance of 100%, 80%, 50% and 20% of productive potential respectively. The Queensland Government is currently funding a six-year program to map grazing land condition in key Great Barrier Reef catchments. The work incorporates assessment of thousands of grazing land sites using the Land Condition Assessment Tool (LCAT), modelling the ABCD land condition class at those sites and generating modelled land condition maps across the targeted regions. Modelling and mapping land condition across large areas presents some significant challenges. For example, land condition is a multidimensional outcome that can be hard to mathematically fit to a unidimensional scale like ABCD, and spatial data that might predict some of these dimensions is either absent or limited. This has led the project to investigate and trial a number of approaches to delivering land condition mapping. This paper outlines the project's progress and some of our key learnings so far. These include an outline of LCAT sampling to date, an overview of the modelling and validation process and details around the planned rollout of the mapping.

Introduction
One of the key threats to the Great Barrier Reef (GBR) is soil sediment runoff from the GBR catchments, and grazing lands have been identified as a significant contributor to this threat (State of Queensland 2018). The Queensland government currently funds a suite of research and extension projects aimed at protecting the GBR. The Land Condition Monitoring Program is one of these and is tasked with developing maps of grazing land condition for GBR catchments.

Grazing land condition is an established framework for quantifying how well a grazing ecosystem is functioning and is defined as the capacity of grazing land to respond to rain and produce useful forage (Chilcott et al. 2003). Under this framework, sites are classified in one of four classes A (good), B (fair), C (poor) or D (very poor) based on the pasture, soil and woodland condition. Sites in A, B, C and D condition are respectively considered to have maintained about 100%, 80%, 50% and 20% of their original capacity to convert rainfall into useful forage. The system has been used widely in Queensland research, development and extension projects, and has proven a useful tool for engaging land managers around landscape health and productivity.

The Land Condition Monitoring Program involves several activities including upgrading the VegMachine.net website and developing a field guide for identification of important Queensland pasture species. This paper focusses on the land condition mapping component of the program. We outline the process to date for developing land condition layers and discuss several key issues around the work including future directions.

Methods

The project area includes three key Great Barrier Reef Natural Resource Management (NRM) regions (NQ Dry Tropics, Fitzroy Basin Association and Burnett Mary Regional Group). These cover a combined 351 000 km^2. Collection of land condition data in this area began in 2020 and is currently funded to June 2026.

All land condition data in the study were collected using LCAT (Land Condition Assessment Tool (Hassett et al. 2021)), a simple phone / tablet survey tool embedded in the ESRI survey 123 app. LCAT users include field staff of most Queensland NRMs as well as research and extension staff of the Queensland Department of Primary Industries. All users receive LCAT training prior to field use. LCAT users evaluate one hectare grazing land sites, recording data on variables including ground cover, primary pasture species, pasture density, pest species and abundance, woody cover and erosion. The LCAT algorithm then generates a variety of site summaries on-the-fly including a land condition rating (A, B, C or D). These data and summaries are then uploaded to cloud storage where they can be made available for land condition modelling.

The modelling process largely follows that of Scarth et al (2020). The study area is first segmented into polygons with common long term ground cover and woody cover histories. Summary values are then extracted from a large number of existing spatial layers for each segment to serve as the predictors for the land condition model. Where LCAT sites intersect a segment, the summary values for the segment are used in a random forest model to predict the land condition class of the intersecting site. The modelling process generated 30 potential models with varying parameterisations, and a single model was selected by evaluating fit to both holdout and cross-validation data as well as expert evaluation of the mapping on familiar client properties. The final selected model was then used to predict condition in all segments, and these segments were mapped with their predicted land condition class to create the land condition map.

Results

The current iteration of modelling incorporated 4233 land condition assessments, composed of (916, 1268, 1592 and 457 A, B, C and D condition sites respectively. Ten percent of these were randomly assigned to holdout validation data and the remainder used for model training. The final model incorporated multiple spatial predictors, but the most influential related to long term Dynamic Reference Cover Method value (Bastin et al. 2012), historical rainfall, temporal trend in woody vegetation cover, topography and historical ground cover. Table 1 shows the fit of the model to the holdout data. The ordered Kappa statistic for this fit (suitable for ordinal data) was $\kappa=0.52$, indicating moderate agreement between observed and predicted land condition class. The model predicts C and D condition relatively well, but fewer A and B condition sites are correctly assigned. Figure 1 shows an example section of the imagery.

Table 1. Confusion matrix for numbers of predicted vs observed land condition classifications from final land condition model for 423 sites in the holdout dataset.

Observed \ Predicted	A	B	C	D
A	49	20	20	1
B	12	63	41	4
C	8	24	134	8
D	3	4	8	24

Discussion

LCAT has proven a highly effective tool for collecting and collating land condition data in this project. Its key advantage is that it provides a wide set of users with a common set of criteria and rules for consistent assessment of land condition, and the wide user base maximises data available for exercises such as this project. This is a significant improvement on previous land condition studies (e.g. Karfs et al. 2009, Beutel et al. 2021) that relied on multiple datasets from multiple studies, many of which used different methods to arrive at their land condition assessments.

It's worth noting that LCAT data are collected for a number of purposes depending on the collecting organisation. As well as modelling land condition, these purposes include site monitoring, evaluation of sites applying for public remediation funding and assessment of impact by extension providers. This wide use demonstrates the utility of LCAT, but also highlights an important point – that the full LCAT dataset is not a random sample of the landscape. As such the collated points may not represent the true proportion of each condition class in the landscape. This underlines the importance of developing land condition layers that can adequately estimate those proportions for all parts of the landscape.

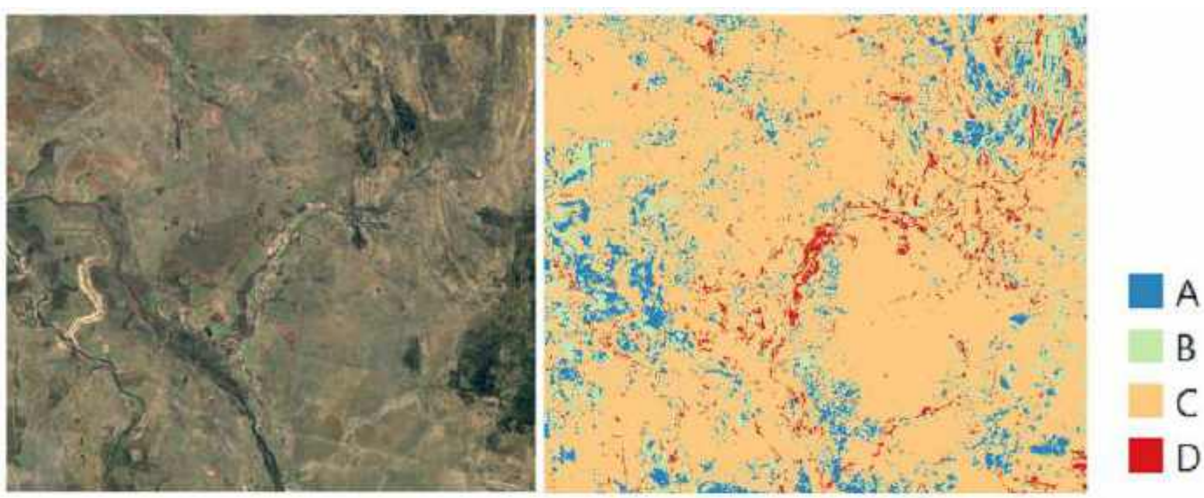

Figure 1. Example section of the current iteration of land condition mapping for a section of the Burdekin region (right) and corresponding RGB image of same area (left).

Table 1 shows the predictive precision of the most recent version of land condition mapping across the entire landscape (we have not yet analysed prediction in subset areas such as individual land types, but work is planned on this topic). While the current model improves on the previous year's iteration (not shown) it also highlights a significant challenge in modelling land condition, and that is the difficulty of correctly detecting high (A and B) condition sites. The current model relies heavily on ground cover related predictors (above), but high ground cover does not necessarily imply good land condition. For example, high coverage of the grass *Bothriochloa pertusa* will produce a C condition rating, at best. We think the model's reliance on ground cover data limits its capacity to distinguish condition classes when cover is relatively high. Conversely poorer condition sites have generally less ground cover than good condition sites, and so the model distinguishes C and D condition sites quite well.

In response to this challenge, we have begun work to model and map the distribution of major pasture species like *B. pertusa*. LCAT surveys include identification of the dominant pasture species so provide a ready data source to map where particular species dominate. If we can map the distribution of such species, these layers could assist in the differentiating condition classes in high cover areas by providing data to the model about pasture composition.

Some of the predictors in our current land condition model are long term (>30 year) ground cover and climatic summary data. These were selected for their predictive capacity, and our thinking is that they may be capturing some of the inherent characteristics of the landscape that have no other surrogates in the predictor set (e.g soil types, climatic zones). Currently it's unclear how long-term predictors will impact our capacity to monitor temporal change in land condition. If these long-term variables mostly describe the context of invariant aspects of the landscape, and shorter-term (≤ 5 years) predictors capture change in condition then its possible long-term predictors will play a useful ongoing role. Ultimately though, the best test of any land condition model's predictive skill is detailed analysis of where and when it does and doesn't predict land condition well, and this is part of the longer term project planning.

The current iteration of the land condition mapping was distributed to a limited audience of extension officers and graziers. These users are providing additional feedback about the mapping. The goal for this work is to publicly distribute future iterations through channels like VegMachine.net once a review of the mapping demonstrates an acceptable level of accuracy and suitable support documentation for users.

Structural diversity in rangelands: a framework for quantifying what makes a functional rangeland

Olsoy, PJ[1]; Copeland, SM[1]; Caughlin, TT[2]; Duquette, CA[3]; O'Connor, RC[1]; Boyd, CS[1]

Key words: ecosystem function, landscape monitoring, sagebrush steppe, unoccupied aerial systems

Abstract

Rangelands across the globe are threatened by factors such as climate change, altered fire regimes, and annual grass invasion, often leading to simplified vegetation structure and reduced ecosystem function. Restoring degraded rangelands to their original state is not always possible given socially acceptable levels of financial and capacity commitment. Whether the goal is to reestablish historically occurring flora and fauna or to mitigate some of the negative impacts of a degraded system, managing and restoring these ecosystems requires knowledge of what makes rangelands multifunctional systems (e.g., grazing, wildlife habitat, recreation) and what causes declines in these ecological functions following degradation. Structural diversity metrics can be used as an indicator of ecosystem function and are now possible to continuously measure across landscapes with remote sensing. Recently, the use of structural diversity from 3-dimensional (3D) spatial datasets has been proposed as a flexible method to measure ecological functions in forested systems but has yet to be applied to rangeland management. We propose using structural diversity to monitor rangeland ecosystem function with two case studies. First, we measure structural diversity across a series of ecological states in semiarid rangelands, from intact shrub and native bunchgrass communities to invasive annual grass-dominated sites and multiple phases of juniper (*Juniperus* spp.) encroachment. Second, we compare structural diversity between paired grazed and ungrazed landscapes. We found that structural diversity differs across ecological states, demonstrating a potential way to assess ecosystem function. With the recent increase in the availability of high-resolution 3D structural data from low-cost unoccupied aerial systems (UAS), structural diversity could be used to help managers rapidly assess the ecological function of rangelands.

Introduction

Recent advances in technologies, such as more widely available LiDAR and low-cost unoccupied aerial systems (UAS or drones) bring new opportunities to understand structure—function relationships (Anderon and Gaston 2013). Researchers in forested ecosystems have begun to explore these relationships, suggesting a theoretical framework focusing on the vertical structuring and niche partitioning seen in these systems (Atkins et al. 2018; LaRue et al. 2023), and linking some of these metrics to ecosystem functions such as productivity (LaRue et al.

2019), but little work has been done in rangelands (see Zaiats et al. 2024), despite demonstrated linkages between structural heterogeneity and ecosystem function using other methods (Maestre et al. 2016). Besides estimating structural contributions to biodiversity, structural diversity could assess fire resilience (e.g., patch arrangement of woody fuels), recovery from disturbances (e.g., post-fire, agricultural abandonment), wildlife habitat, and management treatment longevity. Compared to forested ecosystems, rangelands have less vertical stratification, and therefore different metrics and spatial scales should be considered.

In this study, we provide two case studies demonstrating a framework (Fig. 1) for applying structural diversity metrics to management of rangelands: 1) three ecological states representing intact shrub steppe, invasive annual grass invasion, and juniper encroachment; and 2) a long-term grazing exclosure study (88 years) comparing six sets of paired grazed and ungrazed pastures.

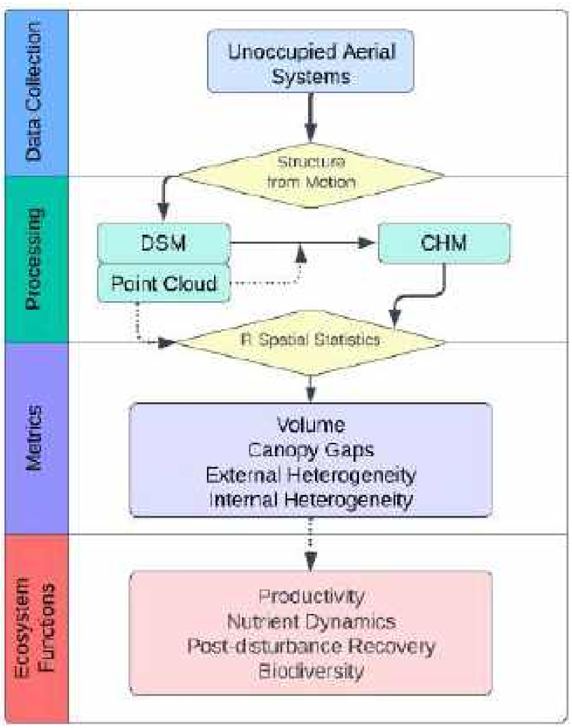

Figure 1. Workflow for generating structural diversity metrics with unoccupied aerial systems (UAS) structure from motion to generate digital surface models (DSM) and canopy height models (CHM).

Methods

We conducted our research at two study areas in southeastern Oregon, USA. The first case study was in the Stinkingwater Mountains (43.63°N, 118.38°W), which contains a range of vegetation communities and ecological states from intact shrub steppe dominated by *Artemisia tridentata*, to post-fire landscapes invaded by medusahead (*Taeniatherum caput-medusae*), to conifer (*Juniperus* sp.) encroached shrublands. The second case study was a long-term grazing exclosure study at the Northern Great Basin Experimental Range (NGBER, 43.48°N, 119.71°W), with pastures covering a range of elevations and vegetation communities with *A. tridentata* dominating the lower elevations and *J. occidentalis* woodlands dominating the higher elevations, but little annual grass invasion compared to the Stinkingwater Mountains.

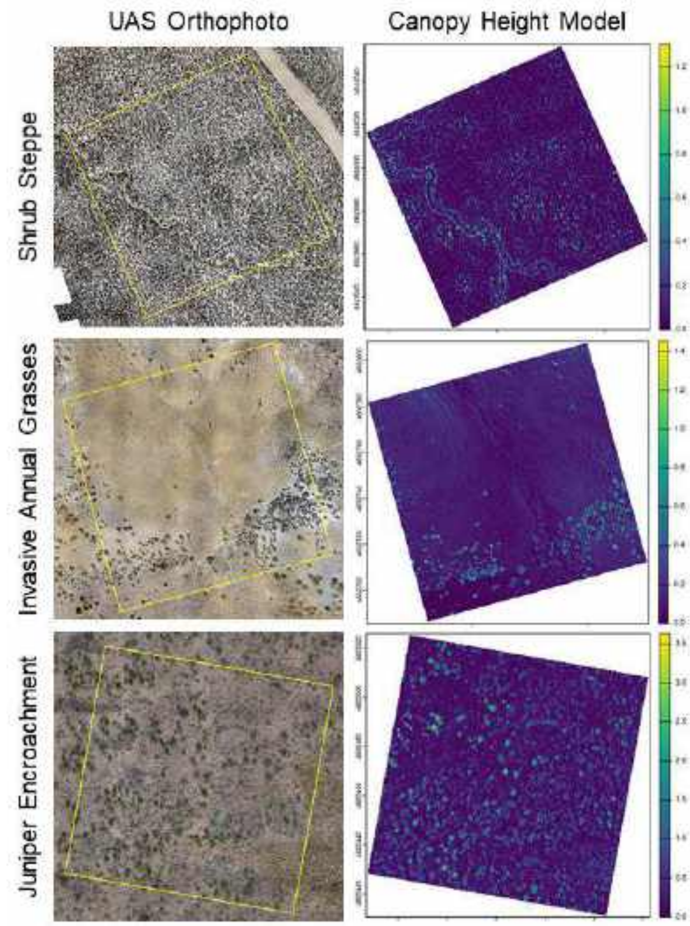

Figure 2. Unoccupied aerial system (UAS) high-resolution orthophotos and canopy height models for three sites in Oregon, USA representing healthy shrub steppe, annual grass invaded, and juniper encroached ecological states. Yellow boxes represent the 100 x 100 m (1 ha) assessed in this study.

We collected imagery with a Freefly Astro (Freefly Systems, Woodinville, WA, USA) UAS equipped with a 61 MP camera. We flew the UAS at 40 m altitude above ground level, with a nadir flight and a 30-degree offset flight with a cross-grid pattern resulting in ~1-cm pixel resolution. We processed the UAS imagery with Open Drone Map (ODM version 3.3) on USDA's SCINet supercomputer Atlas with 48 cores and 320 GB of RAM. ODM parameters were feature-quality and pc-quality set to 'ultra,' min-num-features of 40,000, and orthophoto-resolution and dem-resolution set to 0.01 to obtain the highest pixel resolution from the data. We generated digital surface models (DSM) using structure from motion photogrammetry (Cunliffe et al. 2016; Olsoy et al. 2018). To standardize our structural diversity metric comparisons, we clipped a 100 x 100 m (1-ha) region out of each image for testing purposes. We generated a canopy height model (CHM) by subtracting a ground surface (minimum height on a 1-m moving window) from the digital surface model generated by ODM (Fig. 2). We calculated structural diversity metrics related to volume, openness (gaps), and heterogeneity (internal and external) (LaRue et al. 2019) at a 1-m spatial scale in R version 4.4 (R Core Team 2024) with the terra package (Hijmans 2024). Volume was summed across the 1-ha plot. We calculated the percent of canopy gaps (pixels with less than 15 cm vegetation height) aggregated to 1 m and then averaged across the 1-ha plot. Heterogeneity was calculated as the standard deviation of vegetation heights, with external structural heterogeneity representing the average standard deviation across the 1-ha plot, and internal structural heterogeneity calculated as the standard deviation of the standard deviation of height across the 1-ha plot (LaRue et al. 2019). For the grazed-ungrazed sites (n = 6 pairs), we used paired t-tests to assess differences in structural diversity metrics.

Results

Ecostates

Unsurprisingly, volume was highest in the juniper site with 3610 m^3ha^{-1} compared to both the shrub steppe site (1046 m^3ha^{-1}) and the invasive annual grass site (1480 m^3ha^{-1}). Structural heterogeneity metrics were lowest in the invasive annual grass site (external = 0.046, internal = 0.055) compared to the shrub steppe site (external = 0.096, internal = 0.072) and the juniper encroached site (external = 0.201, internal = 0.151).

Grazing

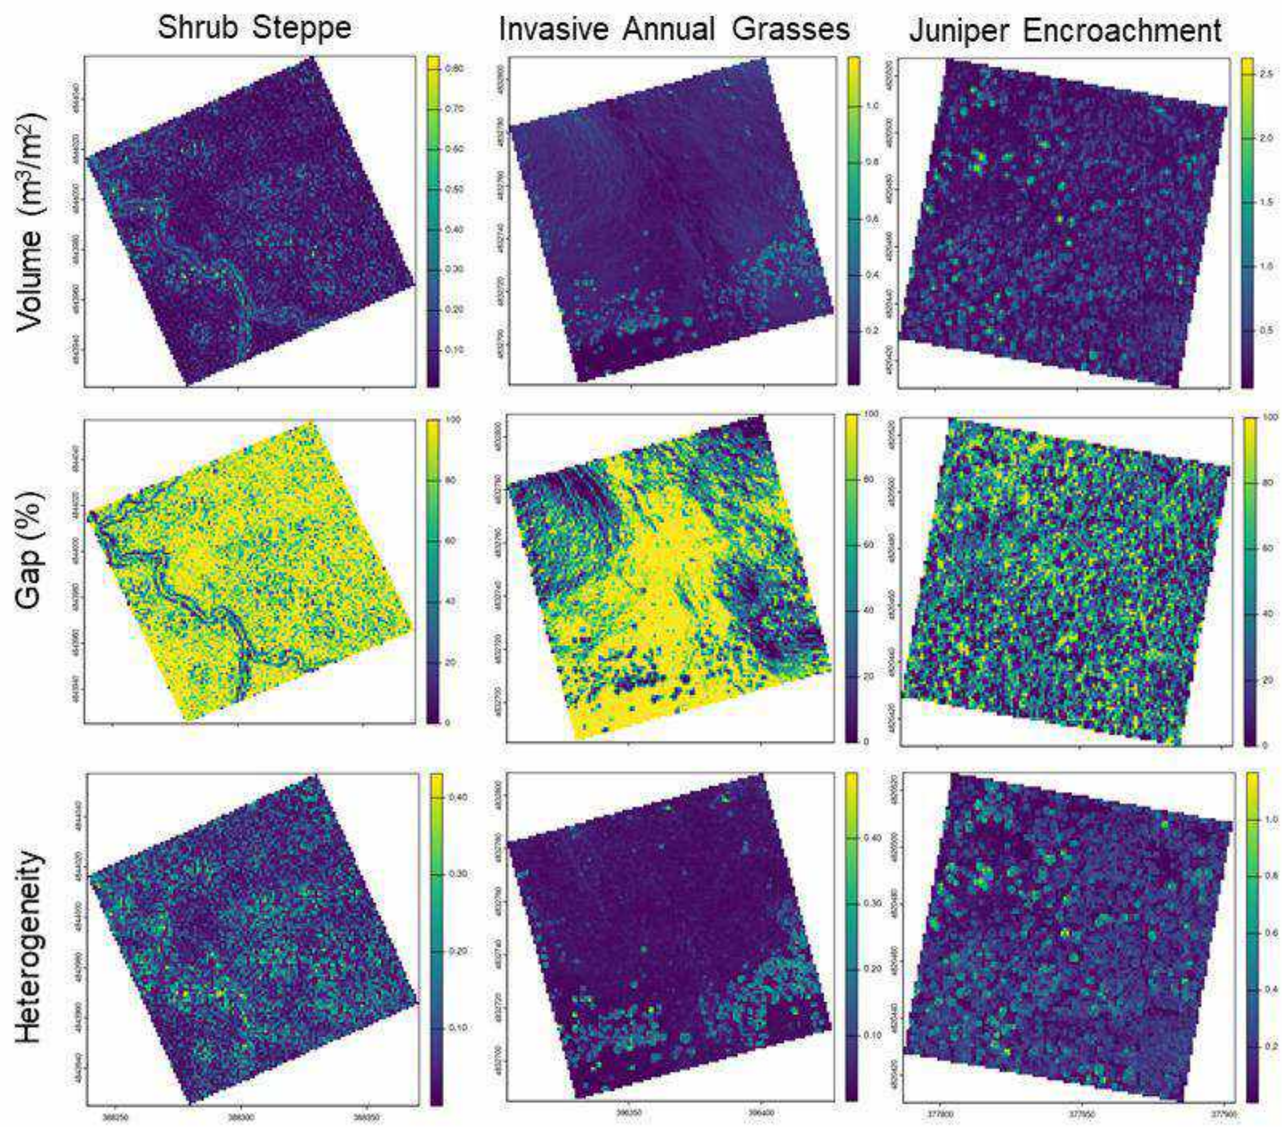

Figure 3. Structural diversity metrics for three sites representing distinct ecological states in Oregon, USA.

We did not find any statistical differences in structural diversity metrics between grazed an ungrazed plots at NGBER. Volume was 4508 m^3ha^{-1} in grazed and 4690 m^3ha^{-1} in ungrazed plots (t_5 = -0.36, P = 0.733). Gap percent was marginally significant with 56% gaps in grazed and 49% in ungrazed plots (t_5 = 2.45, P = 0.058). External heterogeneity was 0.19 in both grazed and ungrazed plots (t_5 = -0.05, P=0.96) and internal heterogeneity was 0.23 in both grazed and ungrazed plots (t_5 = -1.21, P = 0.28). Variability was higher between sites than treatments, for example, the site with the most juniper had 15,458 m^3 volume, while the non-juniper pastures had between 1147 and 1767 m^3 volume. Percent gaps also ranged from 0.1% at the juniper site to over 80% at two of the grazed non-juniper sites.

Discussion

Structural diversity metrics differed across ecological states, with juniper encroached sites having higher volume and less canopy gaps. However, we did not detect structural diversity differences in grazed pastures compared to long-term grazing exclosures, perhaps due to the small sample size (n = 6). The light to moderate grazing at the site could explain our results, which did not lead to differences in species composition (Copeland et al. 2021). The scale we used to calculate structural diversity metrics (1 m) could also be wrong for the ecological process (Levin 2000). The relative contribution of different plant functional types and species to structural diversity is unknown and could shed light on differences in biodiversity and occupied niches, which are undetected when looking at site-level structural diversity metrics. For example, the volume and canopy connectivity seen at the invasive annual grass invaded site is due to large mats of medusahead and indicate high wildfire fuel loading within a degraded system, while similar volume and connectivity in the shrub steppe ecological state represents high shrub cover with less connectivity of fine fuels. Selecting metrics that quantify these differences in wildfire risk and biodiversity is vital (Levin 2000; Ellsworth et al. 2020). Rangelands likely have differences in useful spatial scales (Zaiats et al. 2024) and less emphasis on vertical structural diversity than forests, particularly semiarid rangelands which tend to have lower productivity. However, more productive rangelands such as African savannas or the central plains of USA could demonstrate some of the vertical stratification and utilize the wealth of structural diversity metrics already developed for forested systems.

Future research could explore how metrics change across different scales and seek to directly link structural diversity metrics with ecosystem functions. A few examples of future work are landscape prioritization for fuels management, assessing resistance and resilience after disturbances, and developing workflows and tools to ease the implementation of these across broad landscapes and ease administrative burdens for land management agencies.

Assessing woody plant health in rangeland ecosystems: implications for estimates of aboveground biomass

Piper, MC[1]; England, JR[2]; Paul, KI[1]

[1] CSIRO Environment, GPO Box 1700, ACT 2601, Australia.; [2] CSIRO Environment, Private Bag 10, Clayton South, VIC 3169, Australia.

Key words: Standing dead; Tree health; Plant functional types; Allometry; Rangelands

Abstract

Rangelands are subject to episodic droughts, regular fires and grazing pressure, all of which impact woody plant (tree/shrub) health. Consequently, standing dead and senescent woody plants are key components of these ecosystems. Stand-level, woody aboveground biomass (*AGB*), an important component of the terrestrial carbon budget, is typically scaled using individual-based allometric relationships with predictor variables such as stem diameter or crown area measured through on-ground inventories of woody plants. Current data are lacking to allow assessment of the influence of woody plant condition on allometry and subsequent scaling of *AGB*. To address this, we undertook field measurements across 431 Australian rangeland sites to improve understanding of the variation in the condition of woody plants across rangelands, including how condition of different plant functional types affects overall stand condition, and how stem diameter-crown area allometry varies with condition and plant functional type. Field measurements included stem diameter, crown width and vigour, and health scores of live and standing dead woody plants. Over one-quarter of individual woody plants were either dead or senescing across all sites. Stem diameter-crown area allometric relationships differed among plant functional types, with those found for trees differing from those of shrubs and multi-stemmed acacias. For a given stem diameter, allometry-predicted crown area declined as health score decreased. Our findings suggest that if traditional allometric relationships developed for live, healthy woody plants are applied to predict *AGB* in these ecosystems, substantial over-estimations may result, particularly for stands with a relatively high proportion of woody plants of poor condition. Results will inform ongoing improvements to the accuracy of stand-level biomass estimates in rangelands.

Introduction

Stand-level aboveground biomass (*AGB*) is a key component of the terrestrial carbon budget and typically scaled using allometric relationships with predictor variables such as stem diameter (Paul et al. 2016) or canopy area (Suganuma et al. 2006; Chieppa et al. 2020) measured through on-ground inventories of woody plants. However, most allometric relationships have been developed using young, healthy woody plants (Baker et al. 2004), and there is a paucity of data available to assess the influence of plant condition on this allometry and subsequent scaling of stand-level *AGB*. Uncertainty in *AGB* estimates will result when variance in condition of woody plants within a population to which the allometric relationship is being applied differs from that within the population of woody plants upon which the relationship was originally developed. This leaves a potential over-prediction bias in *AGB* when typical allometric relationships are applied to a population of woody plants containing relatively high proportions of over-mature, or dead woody plants.

In Australia, rangeland ecosystems encompass a broad range of woody vegetation types that are increasingly being monitored to assess the impact of changed climate and management on provision of ecosystems services through estimating changes in *AGB* (Fensham et al. 2011). Further, rangelands are subject to episodic droughts, regular fires and grazing, all of which impact woody plant health (e.g., Fensham et al. 2003; Fensham 2005; Cook et al. 2020). Rangeland ecosystems therefore provide a good case study for exploring implications of health of woody plants on allometry-predicted biomass and subsequent scaling of stand-level *AGB*.

The objectives of this study were to: (i) develop a protocol to quantify plant condition and apply this to extensive plot-based inventories to quantify typical proportions of woody plants that are senescent or dead, (ii) assess how health condition of individual woody plants influences their biomass to inform how allometry-predicted biomass may be adjusted based on condition of woody plants of different types and sizes, and (iii) explore implications of health condition of woody plants on allometry-predicted biomass and subsequent scaling of stand-level *AGB*.

Methods

A total of 431 sites (each 90 m × 90 m) from 51 properties across Australian rangelands were selected to cover a range of rangeland vegetation types. We measured 278,478 individual woody plants for health score of the stem (H_S) and crown (H_C) of live woody plants, or health score of standing dead woody plants (H_D) (Table 1) and recorded plant functional type (PFT, as per Paul et al. 2016), including Shrubs, Multi-stemmed acacia trees, *Eucalyptus* and *Corymbia* (Eucalypt) trees, Mallees, and Other trees of relatively high wood density. Live aboveground biomass of individual woody plants ($AGBi_{Live}$) was estimated from the application of PFT-based allometric relationships described by Paul et al. 2016. Standing dead aboveground biomass of individual woody plants ($AGBi_{Dead}$) was estimated using theoretical PFT-based allometric relationships developed for standing dead woody plants (Paul and Roxburgh 2024), noting that these allometrics were representative of an H_D score of 1. Stand-level total aboveground biomass (AGB_{Total}, Mg DM ha^{-1}) was calculated from the sum of all $AGBi_{Live}$ and $AGBi_{Dead}$ divided by site area.

For each individual tree/shrub, stem diameter (*D*) was measured at either 130 cm (*D130*; trees) or 10 cm (*D10*; shrubs), and the width and length of the crown was measured at the smallest and longest diameters of the crown, respectively. Measurements of crown width and length were used to estimate the crown area of the individual woody plant (*CAi*, m^2), assuming an ellipse.

Influence of condition on crown cover of individual woody plants

Crown vigour of the *CAi*, defined as the percentage of the *CAi* occupied by branches and/or leaves (Table 1), was visually assessed for 1,201 individuals of varying PFT and health score, excluding stumps, across 45 sites covering a range of vegetation types and site conditions. The effect of health score on *CAi* of a given *D* was tested, where *D* is a surrogate of aboveground woody biomass of individual trees/shrubs currently used in existing allometric relationships. Separate relationships were developed for different groupings of PFT, starting with the five PFTs, and further grouping into broader life-forms of 'Trees'

(Eucalypt, Other trees, Mallee) and Shrubs/Multi-stemmed acacias. Analysis of variance was used to test whether crown vigour differed significantly between health scores and life-forms.

D-CAi allometric relationships were developed with the form:

$$CAi = aD^{b} \qquad \text{Eqn 1}$$

where *CAi* was individual crown area (m^2), *D* was *D130* for trees and *D10* for Shrubs and Multi-stemmed acacia, constant *a* was a scaling factor and constant *b* was the exponent, determining rates of growth. Dead woody plants with H_D scores of 4 and 5 where there was no crown were excluded.

Sensitivity of stand-scale allometry-predicted woody biomass to plant health

Sensitivity of allometry-predicted AGB_{Total} to variations in plant condition were assessed by comparing 'uncorrected' *AGB* derived from application of existing allometric equations as described above, with alternative estimates of *AGB* where downward 'corrections' for different health scores based on assumed typical reductions in *AGB* components (stem, branch and foliage) were applied (Table 1). Due to the paucity of information on typical reductions in these components associated with differing health, these corrections were informed using published data on typical allocations to different biomass components (e.g., Forrester et al. 2024; Paul and Roxburgh 2024), and then proportionally reducing all or part of different components in line with the health scores as described in Table 1.

Table 1: Description of health scores applied to crown and stem components of live woody plants and to standing dead woody plants, and assumed corrections for downward adjustment of allometry-predicted biomass used in sensitivity analyses.

Health Score	Description	Assumed corrections[1]
	Live woody plants: Crown (H_C)	
1	Crown very healthy; almost no dead branches	1.00
2	Crown fair; some small dead branches	1.00
3	Crown poor; most small branches dead	0.50[2]
4	Crown very poor; most small branches dead and one or more large dead branches	0.40[2]
5	Crown nearly dead; most small and large branches dead	0.30[2]
	Live woody plants: Stem (H_S)	
1	Stem live, bark intact	1.00
2	Stem live, bark breached/shallow scars but still intact	1.00
3	Stem live, bark breached/deep scars and heartwood exposed	0.30[2]
4	Stem live, but heartwood extremely hollowed or stem mostly dead	0.20[2]
	Standing dead woody plants (H_D)	
1	Dead, with small canopy branches	1.00
2	Dead, with only large canopy branches	0.80[3]
3	Dead, main bole and few large branches remaining	0.50[3]
4	Dead, only main bole remaining or most of stem height	0.10[3]
5	Dead, more than half of main stem missing	0.05[3]

[1] assumptions for downward adjustment of *D*-based allometry-predicted biomass used in sensitivity analyses. Note: A value of 1 indicates no correction and a value of 0.5 indicates a reduction of 50%.

[2] assumptions for H_C and H_S were only applied for for large (*D130* >55 cm) highly-senescent (H_S of 3-4 and/or H_C of 3-5) Euc trees.

[3] assumptions were only applied for dead woody plants (H_D 2-5).

Results

Characteristics and condition of woody plants in rangelands

Across all stands, over one-quarter of individuals were either dead or senescing (mean ± SD: 26.1 ± 23.3%). The proportion of dead individuals averaged 15.9 ± 18.3%; 10.6 ± 16.0% were standing dead (with branches remaining, H_D scores of 1 or 2), and 5.3 ± 9.5% were stumps (only the main stems remaining at various heights, H_D scores of 3-5). The distribution of data for the proportion of dead was strongly positively skewed with only one-third of sites having >16% of individuals being dead.

Influence of condition on crown cover and biomass of woody plants

Crown vigour of individual woody plants significantly (F = 49.12, P<0.001) increased as condition increased. For live trees, crown vigour increased from a mean of 32% at an H_C score of 5, to a mean of 69% at an H_C of 1, and for Shrub/Multi-Ac, increased from a mean of 68% to 88% as condition score improved from an H_C of 5 through to an H_C of 1. Similarly, vigour of standing dead (dead woody plants with branches remaining) increased from 20% to 43% as condition increased from H_D 3 to 1. Within the broader groupings of 'Tree' and 'Shrub/Multi-stemmed acacia', there were no statistical differences (P>0.05) between PFTs.

D-CAi allometric relationships varied between broader life-form groupings of Trees and Shrubs/Multi-stemmed acacias (data not shown). For both live and dead Trees, *D-CAi* allometric relationships differed with condition (Fig.1). For a given *D*, allometry-predicted *CAi* declined as condition declined. Model efficiency (*EF*) of *D-CAi* allometric relationships decreased with decreasing condition (H_C 1-5: EF = 0.63 to 0.32; H_D 1-3: EF = 0.52 to 0.25), largely attributable to differences in sample size for live Trees (H_C 1-5: N = 22,746 to 123), but not dead Trees (H_D 1-3: N = 821 to 1,201).

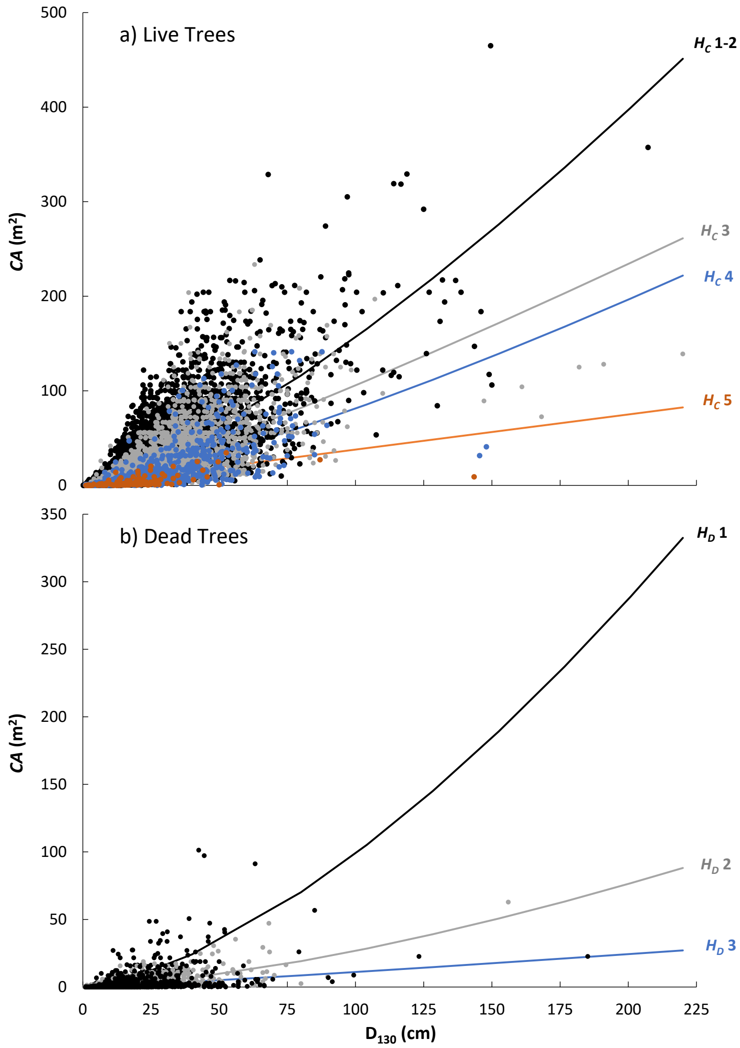

Figure 1. Allometric relationships between stem diameter (*D*) and crown area (*CA*) corrected for crown vigour for the Trees grouping representing the Eucalypt, Other hardwood tree and Mallee plant functional types: (a) live Trees and b) dead Trees. Lines represent fitted power functions. Health scores for live (H_C 1-5) and dead (H_D 1-5) trees are defined in Table 1.

Across all sites (N = 431), allometry-predicted AGB_{Total} was on average 9 ± 12% (but up to 72%) lower when multipliers were applied to account for standing dead and, where present, large senescing Eucalypt trees, relative to existing allometric equations (Fig. 2a). These corrections had a particularly high influence on sites of relatively high biomass (AGB_{Total} > 100 Mg DM ha^{-1}; N = 22), where allometry-predicted AGB_{Total} was on average 34 ± 19% lower after applying the recommended corrections. By comparison, when only considering sites where there were no large senescing Eucalypt trees (N = 317), allometry-predicted AGB_{Total} was on average 5 ± 8% (but up to 50%) lower when multipliers were applied to account for standing dead (Fig. 2b).

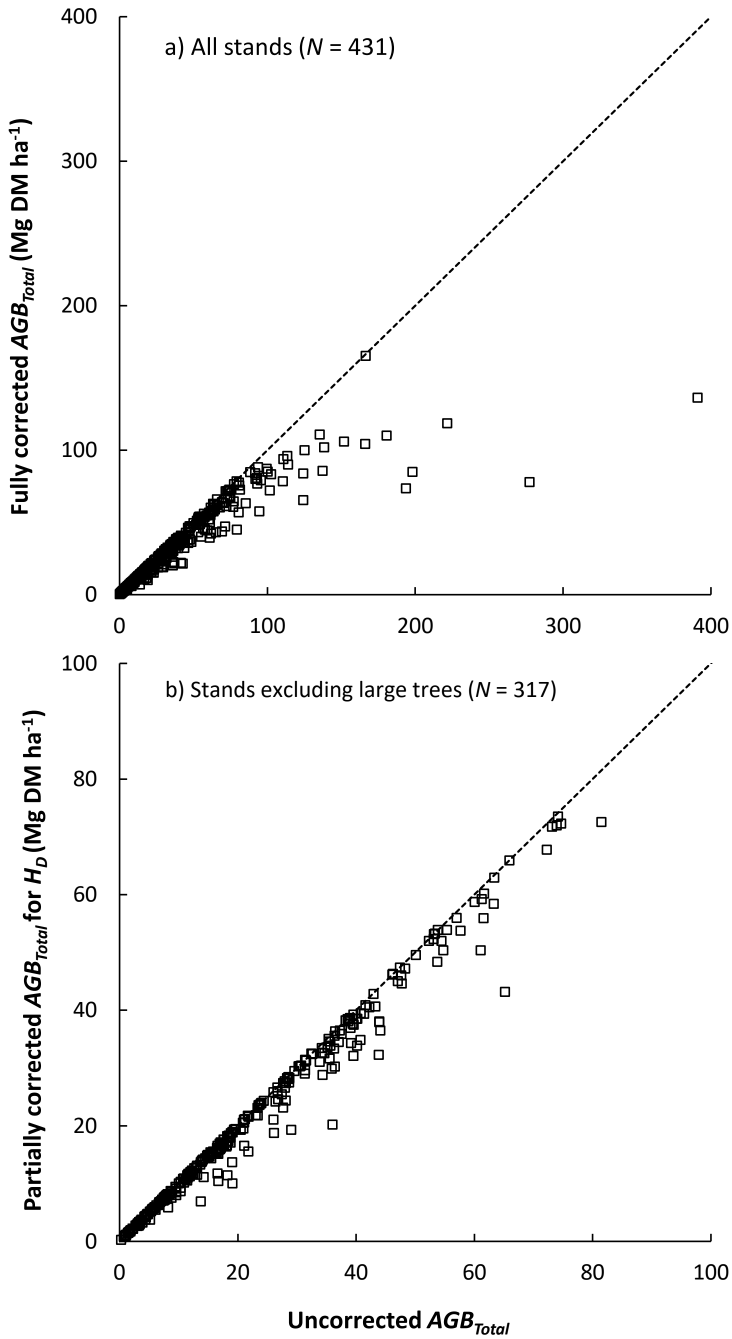

Figure 2. Relationship between uncorrected stand-level allometry-predicted total aboveground biomass (AGB_{Total}, Mg DM ha^{-1}) and AGB_{Total} where a) full corrections were applied to account for H_C, H_S and H_D scores, and where present, large senescent Euc trees, for all of the 431 rangeland sites, and b) AGB_{Total} where partial corrections were applied to account for H_D scores for 317 rangeland sites where there were no large trees (*D130* >55 cm). Corrections are provided in Table 1.

Discussion

A key finding of this study was that across the 431 measured sites, around 16% of individuals were standing dead. A review found in Australian woodlands that 8.1-23.0%, and in dry sclerophyll forests, 0.2–4.5% of total biomass was standing dead (Woldendorp et al. 2002). Mortality events in rangelands tend to be episodic, for example, Fensham and Holman's (1999) survey suggested that ~25% of live basal area was converted to dead standing wood during 5 years of intense drought over a large area of Northern Queensland. Cook et al. (2020) reported that standing dead was 9.6% of total biomass in savannas subjected to regular fires.

This is the first study in rangelands to provide evidence of the influence of health condition of woody plants on their *AGB* – both directly via a significantly lower *D* (and hence, *AGB*) for a given *CAi* (Fig. 1), and indirectly via a significantly decreased *CA* with decreased canopy vigour. Our results suggest that the condition of individual woody plants within rangelands are likely to influence the observed canopy cover of the stand.

Assuming these 431 diverse rangelands stands were representative of Australian rangelands more broadly, these results suggest that if traditional *D*- or *CA*-allometric relationships developed for healthy live trees or shrubs were applied to these ecosystems to predict *AGB*, substantial over-estimation may result, particularly for stands with a relatively high proportion of trees of relatively poor condition. The fact that there was decreasing efficiency in the *D*-*CAi* relationship with decreasing health score of woody plants (Fig. 1) indicated that not only will condition impact the relationship required to predict *AGB*, it will also impact the precision of that relationship. This may be expected because a poor health score is qualitative and will likely encompass varying effects on *AGB* given it will not accurately account for the extent of stem hollowing. Internal hollows within the stem and large branches are typically not visible to the on-ground observer seeking to provide a health score, yet these hollows are likely to substantially influence the actual *AGB*.

Conclusions/Implications

This study provides improved understanding of the variation in woody plant condition across a wide range of rangeland vegetation types, and its impact on allometric relationships, which are critical for predicting woody biomass. To avoid substantial over-prediction of total stand *AGB*, corrections to existing allometric relationships derived from predominantly healthy woody plants are required to account for differences in *AGB* of dead woody plants, and a decline in *AGB* of live woody plants, particularly as they age and over-mature. The results inform improved accuracy of stand-level woody biomass estimates in rangelands.

Key words: dynamic vegetation model; C_3/C_4 vegetation; elevated CO_2 concentrations; elevated temperatures

Abstract

Process-based vegetation models are invaluable tools for understanding and predicting vegetation responses to changes in climate and land management. However, many existing models were developed decades ago and do not incorporate our latest knowledge of plant and ecosystem functioning. Here we present DAVE-Grass, a new dynamic and process-based model of herbaceous vegetation function with a focus on Australian grasslands. The model integrates our latest empirical and theoretical understanding of processes considered to be critical for predicting rangeland responses to changes in climate and management: photosynthesis, growth, carbon allocation, phenology, establishment, persistence, water and nutrient dynamics as well as fire behaviour. It represents C_3 and C_4 plants as well as annual and perennial growth forms which compete for resources such as light and water. The model has been evaluated against data from manipulative experiments, land-atmosphere fluxes, biomass, as well as phenology from phenocams and satellites. In this presentation, we showcase early applications of the model with a focus on the current and projected distribution of C_3 and C_4 vegetation across Australia under different climate change scenarios. The process-based nature of the DAVE-Grass model provides insights into the mechanisms underlying observed changes in vegetation cover and composition. By combining these features with its applicability from site to continental scales, the model promises to be a critical tool for guiding effective management and adaptation efforts in rangelands.

Introduction

Grasslands, including managed pastures, rangelands, and savannas, cover approximately 40% of the global ice-free land surface, act as significant C storage, and fulfil a wide range of ecosystem services (Petermann & Buzhdygan, 2021; White et al., 2000). However, many grasslands are at risk from climate change and intensifying land use and land management globally large areas of grasslands have been identified as degraded to some extent (Bardgett et al., 2021). The increasing pressure on grasslands highlights the need for reliable tools to predict their responses to changes in climate and to identify sustainable management options.

Process-based vegetation models are primary tools to understand ecosystem processes and to predict their functioning under a changing climate (Fisher & Koven, 2020). However, existing process-based models are not well suited to investigate many real-world applications. Dynamic vegetation models often oversimplify crucial processes such as phenology, senescence, and plant persistence (De Kauwe et al., 2017). In addition, these types of models often ignore management routines.

Pasture and grass growth models do account for many management activities, but often oversimplify plant physiological processes. In addition, these types of models were often developed for a specific pasture type and are not applicable across larger spatial scales (Ma et al., 2019).

Here, we present the grassland model DAVE-Grass, a newly developed model that aims to overcome these critical limitations of existing models. We give a short overview of key processes represented in the model and showcase its ability at a grassland site in southern NSW.

Methods

Model description

DAVE-Grass is a dynamic, process-based vegetation model that incorporates key physiological, phenological, and plant demographic processes of herbaceous vegetation. Management routines including grazing, mowing, and irrigation, are currently under development. The model is embedded into the widely used LPJ-GUESS dynamic vegetation model (Smith et al., 2014).

The key processes represented in the model are illustrated in Fig. 1. The model uses absorbed radiation by the canopy to calculate photosynthesis in different canopy layers using the Farquhar et al. (1980) model for C_3 vegetation and the von Caemmerer (2000) model for C_4 vegetation. Plant respiration is calculated as in LPJ-GUESS. The resulting net primary productivity (NPP) is used for either growth or kept as storage in the form of non-structural carbohydrates. The carbon (C) used for growth is allocated to different plant components depending on environmental conditions and plant growth stage. Similar processes govern the plant turnover (senescence) rates. These processes are modulated by competition between plant types, disturbances such as fire, as well as nutrient and water availability. Long-term plant survival and dynamics are represented in the form of mortality and establishment processes.

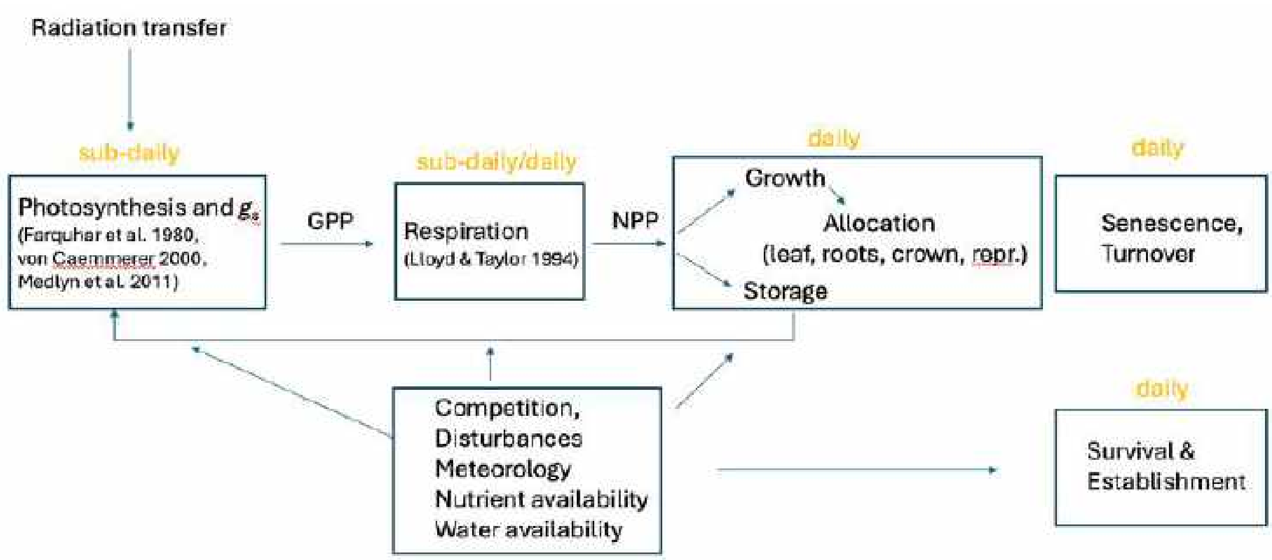

Figure 1: Schematic diagram of the DAVE-Grass model including the most important processes and their interactions.

Site-level application

We present a site-level application of the model at Yanco, an extensively managed, semi-arid grassland site in the western plains of the Murrumbidgee Catchment in southern NSW (latitude: -34.9893, longitude: 146.2907). Mean annual precipitation at the site is ca. 450 mm. More information on the site can be found in Yee et al. (2015). The type or species of grass as well as the grazing intensity are not reported. Meteorology as well as land-atmosphere fluxes of carbon dioxide, water vapour, and heat are measured at the site using an eddy covariance system. Gross primary productivity (GPP) was derived from measured net ecosystem exchange using the SOLO machine learning algorithm.

The model was forced with meteorology measured at the site from 2014 to 2021. In addition to the simulation using measured meteorology (hereafter 'control'), we performed three factorial experiments to analyse ecosystem responses to the main climate change drivers CO_2 and temperature: 1) elevated CO_2 concentrations of +200 ppm ('eCO2'), 2) elevated temperatures of 2 °C above ambient, assuming an unchanged constant relative humidity ('eTair') and 3) a combination of +200 ppm CO_2 and +2 °C temperature ('eCO2_Tair'). All experiments started 8 years before the simulation period in 2006 and were implemented as a step change. Prior to that, the model was spun up using recycled meteorology according to standard model procedures.

Results

Observed and simulated GPP

The daily average measured meteorology of the site is shown in Fig. 2a. At the sub-daily time scale, temperature reaches extremes of >40 °C in summer and < 0 °C in winter. Precipitation is distributed relatively evenly throughout the year. The 2018 - 2020 period is characterised by drier-than-average conditions.

Fig. 2b shows the derived GPP from the flux tower in comparison to simulated GPP by the DAVE-Grass model. Observed GPP shows largely irregular temporal dynamics. While peak GPP occurs mostly in spring, productivity is clearly linked to available soil moisture and the ecosystem can be productive in summer if moisture conditions allow. The model reproduces these flux dynamics moderately well ($r^2 = 0.45$). Notable disagreements between simulations and observations occur in summer and autumn 2016, where the model underestimates GPP. Closer examination revealed that biases in available soil moisture are the primary cause for this discrepancy.

The simulations further indicate that the site is C_3-dominated (Fig. 1c). C_4 vegetation is scarcely present and contributes negligibly to GPP in the summer months.

Climate Sensitivity Experiments

The climate sensitivity simulations revealed that elevated CO_2 concentrations had overall positive effects on both C_3 and C_4 vegetation (Figure 2d). C_3 vegetation achieved higher GPP throughout most of the simulation, though not consistently. Periods of high growth and therefore high water use may lead to subsequent phases of reduced water availability compared to the control simulation, limiting productivity in certain time periods.

Elevated air temperatures had positive effects foremost for C_4 vegetation, which contributed a notably higher proportion to overall GPP in a warmer climate (Figure 2e). C_3 vegetation benefited from elevated air temperatures in some periods but showed declined productivity in others.

The combination of elevated air temperatures and elevated CO_2 concentrations (*eCO2_eTair*) had a strong positive effect on C_3 vegetation during most time periods (Fig 2f). However, as in the *eTair* scenario, productivity declined during a few short time periods compared to the control simulation. This is evident in early summer 2018, when drier conditions occurred compared to the control simulation due to increased water use from autumn to spring 2018. In this scenario, C_4 vegetation remains almost unchanged compared to the control run, likely due to strong competition by C_3 plants.

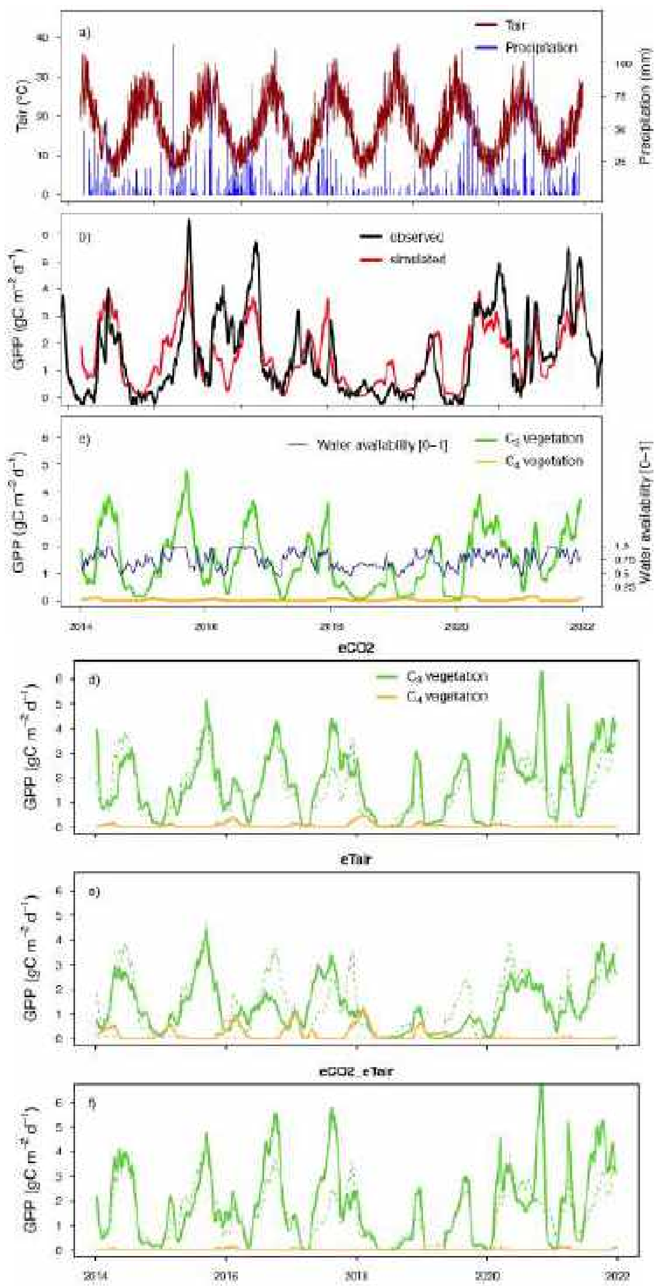

Figure 2 a) Measured average daily air temperature and precipitation at the Yanco site. b) Observed and simulated (control experiment) of gross primary productivity (GPP). c) simulated GPP divided into contributions from C_3 and C_4 vegetation. Shown is also simulated plant available soil water content as a scalar from 0 to 1. Panels d) to f) show the climate sensitivity experiments: d) elevated CO_2

concentrations (+200 ppm), e) elevated air temperatures (+2 °C), and f) a combination of elevated CO_2 concentrations (+200 ppm) and air temperatures (+2 °C). The dashed lines denote the control simulations as shown in panel c.

Discussion

We present a brief overview of the DAVE-Grass model, a newly developed process-based model of herbaceous vegetation functioning. The model includes physiological, phenological, and plant demographic processes that were informed by the latest theory and data and that are commonly ignored or oversimplified in current dynamic vegetation models, especially for herbaceous vegetation (De Kauwe et al., 2017; Wilcox et al., 2023).

The application of the model to the Yanco site, a semi-arid grassland in southern NSW, demonstrates that the current model version can broadly capture the irregular patterns of ecosystem productivity at this location. Nonetheless, further model development is needed to improve the dynamics of vegetation productivity. Improvement should focus on hydrological processes such as soil evaporation and percolation, as well as the sensitivity of vegetation processes like photosynthesis and leaf senescence to water stress.

The climate sensitivity scenarios illustrate that the model predicts beneficial effects of higher CO_2 concentrations for both C_3 and C_4 vegetation. This is likely due to direct CO_2 fertilisation effects for C_3 plants as well as water savings effects due to stomatal closure for both C_3 and C_4 plants (Ainsworth & Rogers, 2007; Morgan et al., 2011). As expected, higher air temperatures benefited C_4 plants (Yamori et al., 2014), whereas a combination of these two factors benefited C_3 plants more than C_4 plants. In all cases, the simulations reveal strong legacy effects, meaning that the past state of vegetation influences its current state.

In summary, this case study offers a foundation for understanding the factors driving vegetation distribution and predicting how these patterns may shift in a future climate.

Key words: vegetation structure complexity; satellite remote sensing; non-photosynthetic vegetation; bare soil; elastic net model

Abstract

Inadequate environmental management in drylands can have serious consequences shifting ecosystems into alternate stable states where key ecosystem services are compromised. Open access Earth observation data can provide continuous and consistent measurements globally, thus providing valuable information on remote dryland locations. The most widely employed remote sensing indicators are spectral indices of vegetation greenness, such as the Normalized Difference Vegetation Index (NDVI) and the Enhanced Vegetation Index (EVI) and are not specifically fit for drylands where background soil has a strong influence and senescent vegetation often dominates. Methodological advances in the past decade now allow the quantification of vegetation fractional cover (VFC) into three categories: photosynthetic vegetation (PV), non-photosynthetic vegetation (NPV) and bare soil (BS). Although monitoring applications have been derived from this product, significant knowledge gaps remain regarding the relationships between vegetation cover fractions and descriptors of ecosystem condition. Our work addressed these gaps at regional and continental scale. At the regional scale we explored links between VFC time series statistics and field measurements of woodland ecosystem quality (soil health and vegetation structure complexity) and elastic net regression to assess combinations of fractional cover statistics for predicting ecosystem quality. We found that time series statistics were robust predictors of soil health and vegetation structure complexity. At the continental scale we demonstrated how vegetation structure components (i.e. woody and herbaceous cover) can be accurately predicted by VFC time series statistics (RMSE<14.75%). Moreover, we found links between field-measured vegetation structure complexity metrics (i.e., growth form and height class diversity) and different combinations of cover-fraction time-series statistics depending on vegetation type and climate.

Introduction

Drylands are vulnerable to degradation due to inadequate land management practices and climate change (D'Odorico et al. 2013). Monitoring methods that enable access to these large and remote areas are needed to inform more sustainable land management practices that can adapt to a changing climate. Multi-spectral satellite remote sensing can be a suitable technique to systematically collect information in dryland ecosystems. A large majority of the methods employed so far relied on vegetation greenness as an indicator of ecosystem health (Soubry et al. 2021). However, drylands are often dominated by senescent vegetation that is hard to separate from soil signals in terms of visible and short infrared wavelength reflectance (Roberts et al. 1993). Moreover, vegetation in this state can still provide crucial functions in drylands such as protecting the soil from erosion (Ludwig et al. 2005), and forage and habitat provision (Moore et al. 2004; Zou et al. 2016). Methods have been developed in the past decade that estimate vegetation fractional cover (VFC) i.e., the proportion of photosynthetic vegetation (PV), non-photosynthetic vegetation (NPV) and bare soil (BS) (Guerschman et al. 2015). Consistent and continuous observation of such features not only allows to track directional change but also deepen the knowledge on temporal dynamics in dryland systems (Francis et al. 2023; Shumack et al. 2021).

The combination of remote sensing products and field observations of ecosystem condition is a fundamental step towards robust monitoring schemes that facilitate adaptive land management (Lawley et al. 2016). Several attempts of modelling vegetation/rangeland condition from remote sensing have been made with varying degrees of field data integration (Lawley et al. 2016; Retallack et al. 2023). In Australia, VFC time series data are increasingly being employed to this end (Department of Environment and Science 2021; Love et al. 2020; Williams et al. 2021). However, only the 'Spatial Biocondition' classification model was trained and evaluated employing over 9,000 field observations within the state of Queensland (Department of Environment and Science 2021). Moreover, links between VFC statistics and the variables that determine condition (e.g., vegetation structure, phenology and ground cover dynamics) have not been thoroughly explored.

Here we employed open-source field observations to explore relationships between time series statistics of remotely sensed VFC and dryland ecosystem condition. Our analyses aimed to answer two main questions:

1. How well do VFC time series statistics predict semi-arid woodland ecosystem condition? Which variables are more important?
2. How well do VFC time series statistics characterise vegetation structural complexity across multiple vegetation types and climatic regimes?

Methods

We obtained ecosystem condition indicators depicting woodland soil health and vegetation structure complexity of 450 'NSW grazing study' sites (State Government of NSW and NSW Department of Climate Change 2023). Soil health indicators were related to soil surface characteristics (i.e., landscape function analysis – nutrient cycling index (Tongway and Hindley 2000)) and topsoil physicochemical properties (i.e., total C, total N, total P and bulk density (Eldridge et al. 2016)). Structural complexity was obtained as an index following Val et al. (2018).

Further characterisation of vegetation structural complexity was undertaken based on TERN Ausplots surveys from dryland (i.e., areas with a rainfall to potential evapotranspiration ratio lower than 0.65) rangelands across the Australian continent (Munroe et al. 2021; TERN 2024). Point-intercept data of 740 plots were processed into woody and herbaceous fractional cover, and five metrics of structural complexity: height coefficient of variation (heightcv), growth form Shannon diversity (GFdiversity), height class Shannon diversity (HCdiversity), plot scale vegetation volume (vegvol, obtained as the product of average height and total cover), and volume coefficient of variation (volcv). Sites were classified according to combined major vegetation groups (NVIS Technical Working Group 2017) and agroclimatic zone (Hutchinson et al. 2005).

Time series of Landsat fractional cover (Joint Remote Sensing Research Program 2021) spanning 5, 10 and 30 years before field sampling were extracted for all overlapping pixels of each 'NSW grazing study' site. Time series statistics (seven for each cover fraction) were then calculated. Apart from typically used central tendency metrics (mean and median) we explored measurements of stability (standard deviation), persistence (intra and inter-annual minima), and dominance (intra and inter-annual maxima). Preliminary analysis showed little difference in model performance among time series extents; the process above was repeated for AusPlot sites using 10-year time series.

Models of woodland ecosystem condition indicators and vegetation structure were fitted through elastic net regression, a method for fitting multiple regression in cases where predictors are highly correlated employing coefficient shrinkage (Zou and Hastie 2005). Optimum parameters (α and λ) values were obtained (from a list of 275 possible combinations) through 250-fold cross validation. Model performance was assessed on the entire dataset through the root mean square error (RMSE) for accuracy assessment and the normalised RMSE (NRMSE = RMSE/standard deviation of observed values) for predictive power comparison across different variables. Models with NRMSE values close to 1 have null predictive power. Coefficient values and selection frequency of predictors across the candidate models were used to assess their importance.

Results

Woodland ecosystem condition

VFC time series yielded good models of woodland ecosystem condition (Figure 1). Although NRMSE was often well below 1, models of soil chemistry were the most accurate. Time series statistics of all cover fractions were found to be important predictors in elastic net models of ecosystem quality variables. Soil C and N were highly correlated with each other, thus shared the same main predictors (i.e., PVmedian, PVmean). Soil P was also related to C and N, however it was more strongly predicted by the annual maximum of green vegetation and negatively influenced by the annual persistence of the dead fraction. The average interannual minimum photosynthetic vegetation fraction was the most important remote sensing predictor of vegetation structure complexity and nutrient cycling index, as it was the most frequently included variable and displayed the highest relative importance in the tested models. Even though vegetation structural complexity displayed a moderately high NRMSE (>0.65), elastic net models were capable of distinguishing between low, medium, and high levels (Figure 1). This result encouraged more detailed analysis of vegetation structural components and continuous measurements of its complexity.

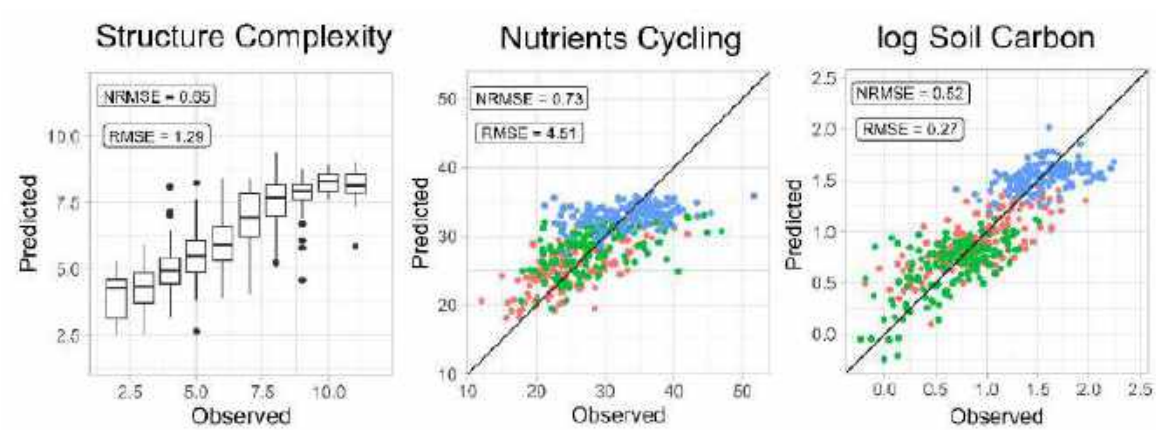

Figure 1. Box and scatter plots of modelled against observed values of the vegetation structural complexity index (dimensionless, left), the nutrients cycling index (dimensionless, centre) and the natural logarithm of soil carbon content (%, right). Root mean square error (RMSE) and its normalization by the standard deviation of observed values (NRMSE) are shown for all 3 models. Different colours indicate different woodland communities (i.e., blue = river red gum, red = black box, and green = white cypress pine).

Vegetation structure and structural complexity

Elastic net modelling based on Landsat fractional cover produced low-bias models of vegetation type cover across dryland ecosystems (Figure 2). Woody cover was more accurately modelled than herbaceous cover. Different fractional cover statistics were important for the prediction of vegetation cover type. In woody cover models, time series statistics related to both inter-annual and intra-annual variability were important. Variables related to the persistence of the green fraction were the most frequently included and most important positive predictors, whereas statistics related to the occurrence of high levels of bare soil were also important but negatively related to woody cover. Herbaceous cover was positively related to statistics describing the variability of both dry and photosynthetic vegetation.

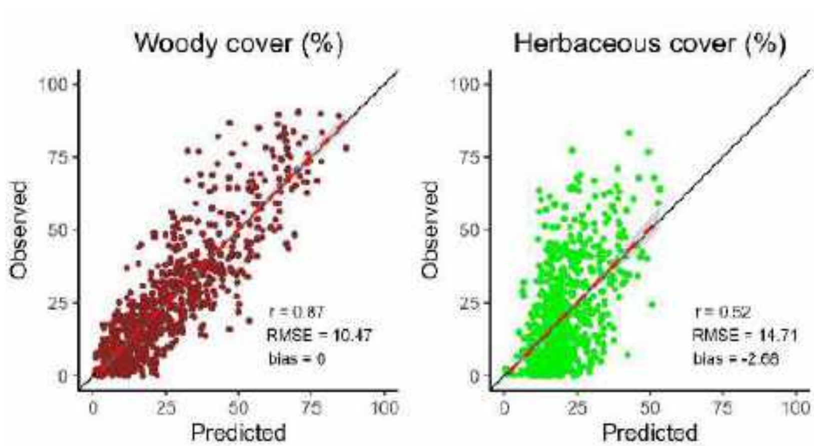

Figure 2. Scatterplots showing the observed and estimated woody component (left) and herbaceous component (right) of 740 AusPlot sites across the Australian drylands. The black line corresponds to the 1:1 agreement, the red dashed line represents the best linear fit between predicted and observed values. Pearson's correlation coefficient (r), root mean square error (RMSE), and bias (calculated as the mean difference between observed and predicted) are displayed.

VFC time series statistics produced structure complexity models of varied performance at the continental drylands scale (Figure 3). Elastic net models of vegetation volume and height class diversity performed the best, other models had an error close to the sample variability (i.e., NRMSE > 0.85). Models calibrated within specific vegetation - climatic groups were able to satisfactorily predict these metrics (NRMSE < 0.72). The most important predictors of HCdiversity were related to the occurrence and persistence of green cover and had positive coefficient values, while the temporal stability of the non-photosynthetic fraction was positively related to HC diversity. Vegetation volume was strongly related to the persistence of the remotely sensed green vegetation fraction. Predictor importance across specific vegetation-climate group models was variable.

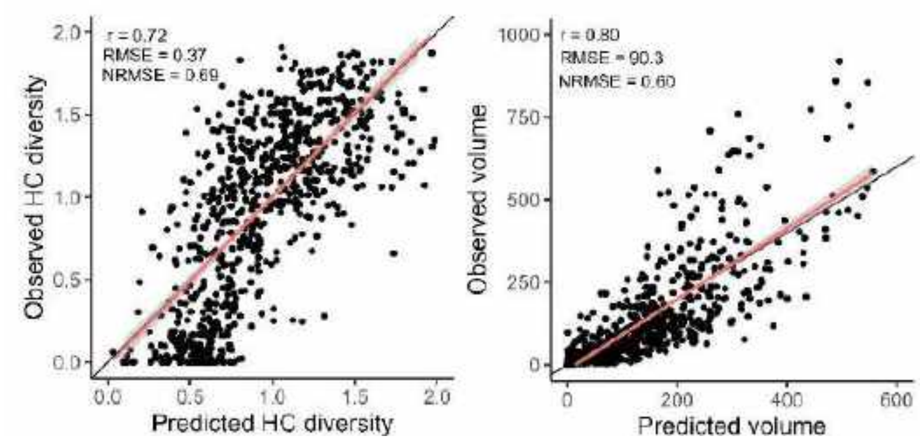

Figure 3. Scatter plots of observed versus modelled structure complexity indicators of all plots (n=740). Vegetation volume is expressed as the product of cover (%) and height (m). The black line corresponds to the 1:1 agreement, the red line represents the best linear fit between predicted and observed values.

Discussion and Conclusions

Variable importance for ecosystem condition indicator models in this study accord with assumptions and findings of previous research, but also revealed new insights. Metrics related to the dominance and stability of remotely-sensed green vegetation were important predictors of structure complexity, the nutrient-cycling index, soil carbon and soil nitrogen in woodlands. This aligns with the criteria employed by expert knowledge-based habitat condition models (Harwood et al. 2016; Love et al. 2020; Williams et al. 2021) and the evaluation of more complex data-driven models of 'BioCondition' (Department of Environment and Science 2021). Accordingly, long term seasonal averages of PV have been identified as important predictors of top-soil organic carbon, surpassing descriptors of climate, lithology and relief (Wang et al. 2018). Moreover, these metrics were also important for woody cover models at the continental scale and agrees with previous methods for modelling tree cover (Gill et al. 2017). Conversely, time series metrics of BS and NPV were often negatively related to woodland condition. This followed expectations, as the dominance and variability of BS in semi-arid woodlands are often respectively related to areas of consistently low and frequent heavily grazed vegetation cover, both cases resulting in poor vegetation structure and degraded soils (Eldridge et al. 2017; Val et al. 2018). Bare soil metrics were also previously identified as important predictors of biological condition class (Department of Environment and Science 2021) and top-soil organic carbon (Wang et al. 2018). The temporal variability of PV and NPV were positive predictors of herbaceous cover at the continental drylands scale, reflecting the seasonal behavior of C4 dominated grasslands (Munroe et al. 2022). This was evident in models of heightCV in savannah woodlands where the stability of BS and persistence of PV were important predictors negatively related to this indicator of structural complexity reflecting that the herbaceous stratum is either absent or overshadowed (in terms of relative cover) by the woody component.

Our research demonstrated the relevance of Landsat VFC as a strategic tool to monitor dryland ecosystems. We found significant and ecologically interpretable relationships between time series statistics of satellite observations of PV, NPV and BS and field observations of vegetation structure and structure complexity, and soil health. Our results set a robust basis for the identification of metrics to monitor the state of different dryland systems, and support informed selection of variables for data-driven modelling techniques.

What standard error metrics don't tell us about model performance – a fractional cover use case

Watson, F[1]; Denham, R[2]

[1] Queensland Department of Environment, Science and Innovation; [2] Joint Remote Sensing Research Program.

Key words: spatial prediction models; remote sensing; fractional cover

Abstract

Environmental monitoring by land managers and land administrators using remote sensing has entered the era of big data, machine learning and open data. Remotely sensed data are commonly used in models as predictors for machine learning algorithms trained on field observations, to develop new products and applications as more data and greater computing power become available.

Despite the wealth of remote sensing data, it is often difficult to obtain representative reference data for these applications, and complete coverage of the predictor space is rare. Users are left to assume that the model outputs will apply to regions where reference data are unavailable. This can result in situations where stated accuracy and error metrics show good model performance, however at a local and possibly regional scales, the map products may not be representative of the true state and therefore not serve its intended purpose. Users of new remote sensing products and applications need to be aware of the uncertainty inherent in the products they use.

In this paper, we present an approach to communicate uncertainty by adding a spatial component to performance metrics by applying the 'Area of Applicability' (AOA) of spatial prediction models, to the Joint Remote Sensing Research Program's Fractional Cover 3 (FC3) product.

The FC3 product is widely used in research and applied settings to monitor vegetation cover and bare ground and inform other models such as pasture biomass or land condition across Australia's rangelands. It is imperative that we continue to improve our understanding of fractional cover models, and their strengths and limitations, to provide appropriate advice and direction to users who are reliant on these data. It can also help to inform future investments in field data collection or other methods of training data collection.

Introduction

The geographic coverage and repeatability of remotely sensed monitoring approaches are useful characteristics to overcome the challenge of monitoring Australia's rangelands, which cover more than 80% of the continent (ACRIS, 2008). The Joint Remote Sensing Research Program Fractional Cover 3 (FC3) product is one such approach which models the percentage of bare ground, photosynthetic vegetation and non-photosynthetic vegetation for each pixel. The model is built upon a collaboratively sourced database of field observations gathered by stakeholders across Australia, mostly within the rangelands.

As for many spatial prediction models, these training data may not meet the ideal standard of representativeness, due to practical constraints over its collection. This results in increased uncertainty in environments that are unsampled or under sampled, which is difficult to communicate to users of the product. The Area of Applicability (AOA) approach of Meyer and Pebesma (2021) is a useful tool that can enable us to better understand the limitations of the FC3 product, providing a method to assess the area to which the model can be reliably applied, and conversely providing insight into those locations which are not well represented. This also extends our ability to communicate uncertainty by adding a spatial component to performance metrics.

Methods

For this example, the methodology of Meyer and Pebesma (2021) was applied, with minor variations. Rather than assessing the AOA in-situ during model fitting we have performed a post-hoc assessment of an existing model by replicating as closely as possible the original model fitting procedure.

Two datasets are used in this example. The first is the training data for the FC3 model, consisting of approximately 4000 field observations of fractional cover collected across Australia between 1997 to 2018 following the method described in Muir et al. (2011). These have been matched to the nearest date, clear Landsat 5 TM,7 ETM+ or 8 OLI overpass, and the surface reflectance values calculated using the procedures described in Flood et. al. (2013), for a 3x3 pixel window. The second is the remotely sensed imagery for which fractional cover predictions can be made, which were Landsat seasonal composite reflectance mosaics for Australia, produced using the methods described in Flood et al. (2013), and Flood (2013), between winter 2014 and winter 2024 (DES, 2021-2024).

The AOA concept attempts to define the area in predictive space for which the model's performance is relevant. That is, the published model performance metrics are only appropriate when a location's characteristics are similar to the locations used to train the model. For each new location the Euclidean distance in predictor space to each of the training data points is calculated. Further, the distances are weighted by the model variable importance scores, under the assumption that locations further away in an important variable should be considered more serious than locations further away in a less important variable. Here, weights were based on SHAP (SHapley Additive exPlanations) scores (Lundberg & Lee 2017). The dissimilarity index (DI) is defined as the minimum of these distances. Those locations in which the DI is greater than a threshold are defined to be beyond the AOA. The threshold is determined by examining the distribution of the DI calculated in the training data under cross-validation. We follow Meyer and Pebesma's (2021) suggestion of a threshold set at the 75-percentile plus 1.5 times the interquartile range (IQR) of the DI values of the cross-validated training data.

Since the distribution of DI are based on cross-validation, the method is sensitive to the type of cross-validation used. There is some evidence that, when training points are spatially correlated, the common *k*-fold cross-validation leads to overly optimistic results. Conversely, spatial cross-validation, such as block cross-validation, has been found to be overly pessimistic. To account for the spatial structure in the sampling data but avoid under-estimating performance, we chose to use *k*-fold nearest-neighbour distance matching cross-validation (*kNNDM)* (Linnenbrink et al 2023).

A sequence of seasonal (four per year) surface reflectance composites between 2014 and 2024 were used as a proxy for representative conditions for which we would likely require predictions. A corresponding DI and AOA map was derived from each one and the full set of 40 seasonal AOA maps then summarised as a frequency map representing the proportion of seasons that a location was outside the AOA.

Results

The results of the kNNDM cross validation are shown in Table 1, for the three cover fractions which the FC3 model predicts. The DI threshold to define AOA was calculated using the same cross-validation folds and found to be 0.128. This threshold was applied to the DI images computed from seasonal composites between winter 2014 and winter 2024, and the AOA summary map shown in Figure 1 produced.

Table 1: kNNDM Cross-validation results.

	Bare (% Cover)	Photosynthetic Vegetation (% Cover)	Non-photosynthetic Vegetation (% Cover)
Root Mean Square Error (RMSE)	13.1	10.0	15.4
Mean Absolute Error (MAE)	9.6	7	11.6

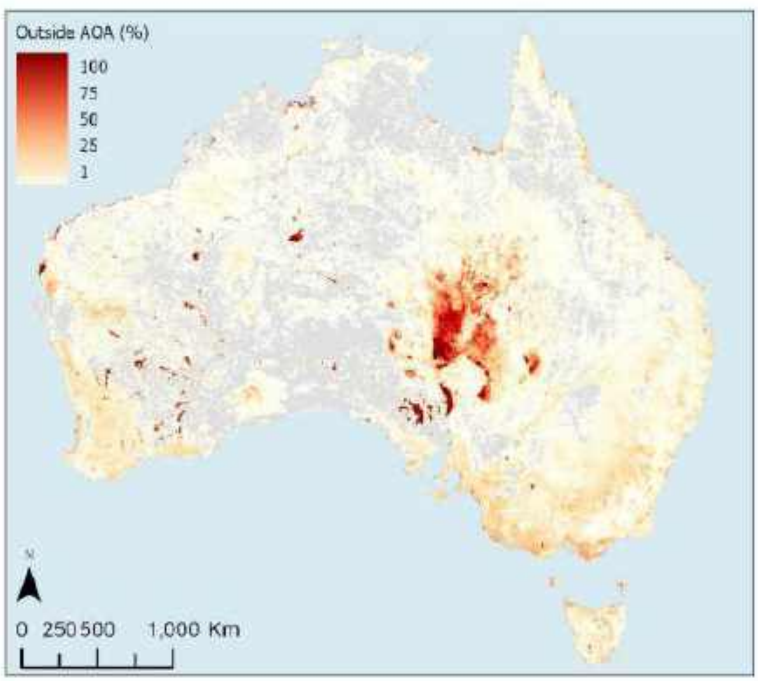

Figure 1 Percentage of seasons in which the surface reflectance was found to be outside the AOA of the FC3 model, 2014 to 2024. Locations that are always within the AOA are grey.

On average less than 10% of Australia is outside the AOA, and less than 5% is frequently outside the AOA (i.e. >50% of the time). Based on visual inspection of the summary map, the areas frequently outside the AOA often appear to be locations where either bare ground or high green vegetation cover dominate, or where cover is highly dynamic, such as the central deserts and salt lake regions, coastal areas and cropping or modified pastures across south-eastern Australia and south-western Western Australia. The bare ground category represents a variety of features including beaches, mudflats, claypans, saltpans, rocky areas and soil of diverse geologies, presumably spectrally distinct from other 'bare ground' locations sampled within the model training data. The high green vegetation cover category is unsurprising, as field site selection has mostly targeted rangeland environments dominated by open native vegetation as per the original intended use of this product. While Australian rangelands can have brief periods of high green cover, these are poorly sampled due to access constraints.

Additionally, all the major cropping regions of Australia show a moderate percentage of seasons outside AOA. This is also unsurprising given that cropping areas may cycle through bare and high green cover states, and in some locations soil moisture from irrigation may also modify the spectral response. Additionally, calibration sites within cropped locations represent a small component of the training data. Further investigation could explore any relationship between specific stages of the crop cycle and DI.

Figure 2 shows exemplar locations outside the AOA. The upper images a) and c) show the DI images for a cropped field and an area of bare soil respectively. The corresponding plots b) and d) below illustrate the spectral space covered by the training data (shown in pink) and the exemplar yellow polygons (shown in blue), as pairwise relationships between each band used for model fitting. A density distribution plot for each band is also shown. The limited overlap between the two sets of points in each example shows that the training data lacks coverage for these features, and that the AOA approach has yielded sensible and interpretable results.

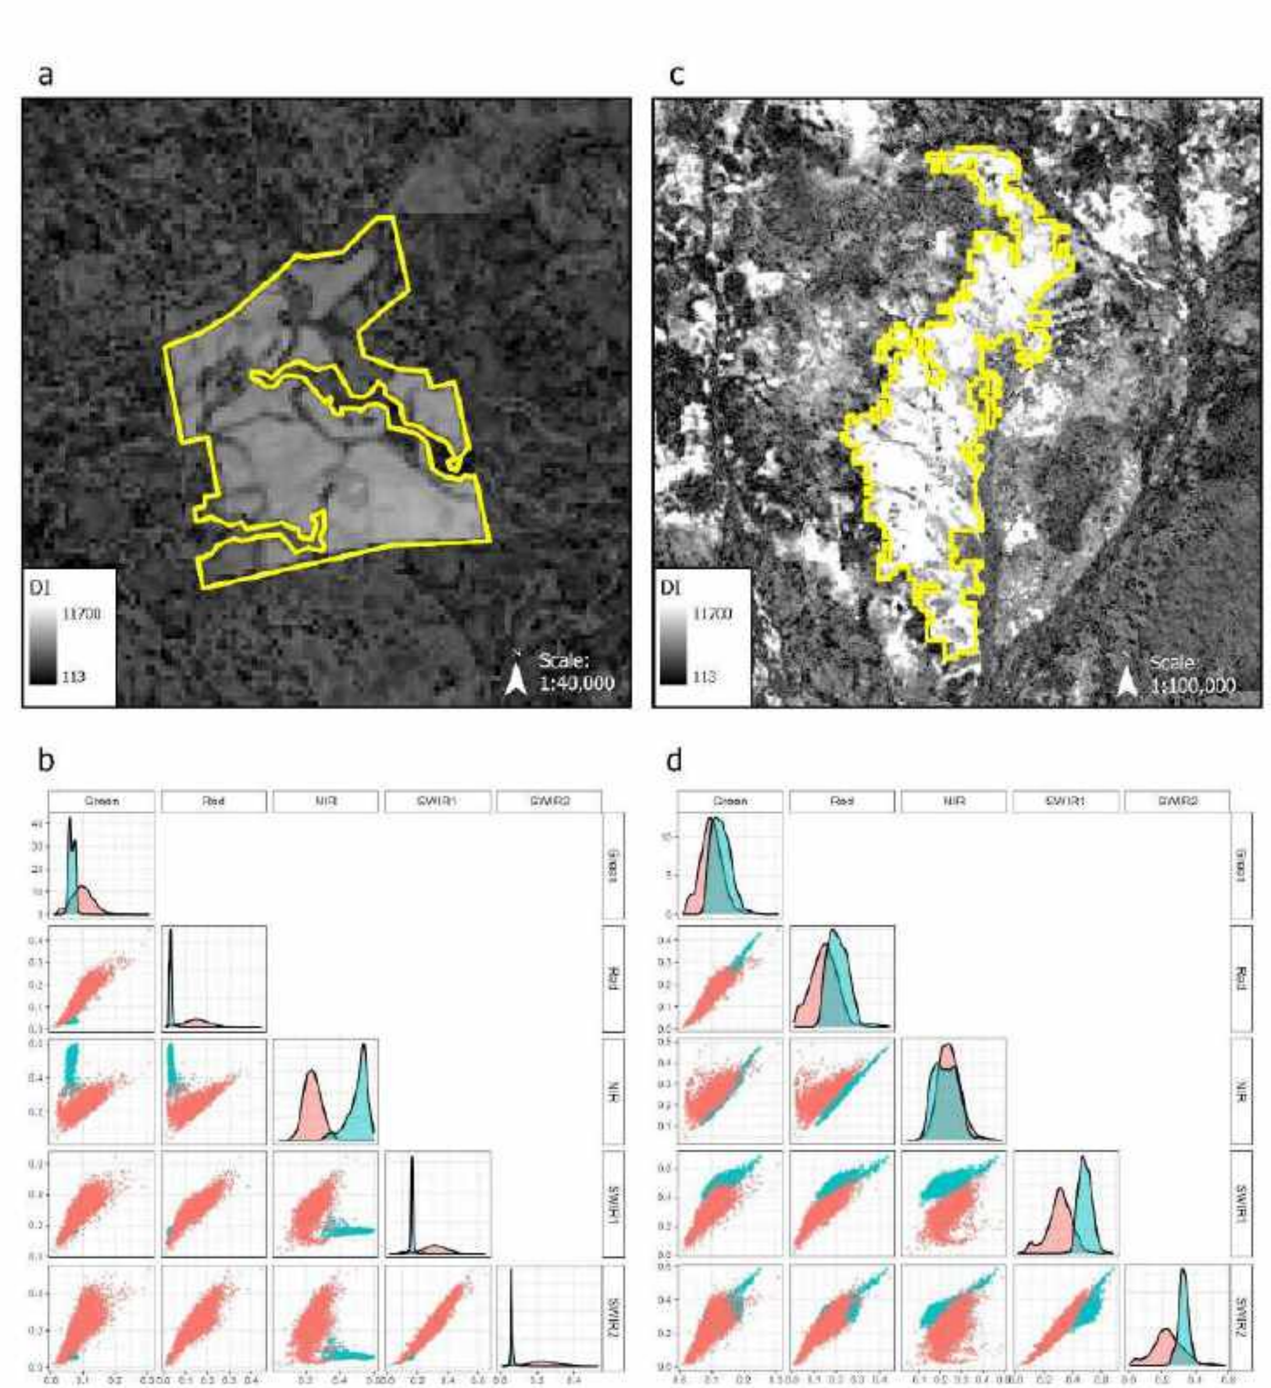

Figure 2 Examples of locations frequently (> 80%) outside AOA (yellow polygon), and comparison of their reflectance with the model training data: (a) DI image for a cropped field in north Queensland; (b) pairs plot of reflectance values for training data (pink shade) and pixels within the yellow polygon in (a) (blue shade); (c) DI image for bare soil in the Channel Country of far western Queensland; and (d) pairs plot of reflectance values for training data (pink shade) and pixels within the yellow polygon in (c) (blue shade).

Discussion

The AOA frequency product presented, provides an aid to users to assess the suitability of the FC3 product for their purposes. Areas which are frequently outside the AOA should be treated cautiously, as the error metrics provided for the product are not applicable here. It should be noted that this does not mean that the model is wrong in these locations, rather that we are unable to say anything about the likely performance in these areas.

The application of the AOA methodology to the FC3 model has proven to be a useful tool for understanding the representativeness of the underlying training data and the corresponding limitations imposed on model performance. It extends the information derived from typical performance or error metrics by giving a spatially explicit extent to which those metrics apply and identifying locations that are not represented by the training data and for which model performance is therefore unknown.

In this case we have shown that while the training data are relatively sparse for a model applied across such a broad geographic area, most of Australia is within the AOA. It is hoped that by making the AOA summary layer publicly available, the diverse users of the FC3 products can better understand how the limitations of the model may impact their intended uses of the product.

Given the FC3 model is applied in an ongoing operational context, an additional insight gained through this work is knowledge about where new calibration field data could be collected, to expand the AOA for future model iterations.

Better Connected: building connectivity skills towards technology adoption to support rural, regional, and remote business and community.

Hay, R[1]; Wilson, CA[1]; Harrington, W[1]; Sparrow, K[2]

[1] James Cook University, Townsville QLD; [2] Better Internet for Rural Regional and Remote Australia, Malden Station, Alpha QLD

Key words: agricultural technology; connectivity literacy; internet; rural, regional, remote; internet-based tools; communications.

Abstract

Connectivity Literacy encompasses all the knowledge needed by a consumer to understand how to get connected and stay connected to equitable, affordable and reliable voice and broadband internet services that meet their needs and budget. It is a precursor to Digital Literacy and incorporates the knowledge needed to navigate through choice of telecommunications providers and technologies, and to understand terminologies, plans and equipment. Connectivity Literacy is challenging in rural, regional, and remote (RRR) Australia and does not have any demographic barriers such as age, gender, location, or education level.

A mixed methods approach using thematic and secondary data analysis was conducted using ten years of data collected to understand the use and understanding of internet services by women, farmers and small to medium enterprises in rural, regional and remote regions across Australia. Surveys, reports and submissions provided quantitative and qualitative data. Thematic analysis was performed on open-ended questions within the data sets, written text and through documented case studies. The findings were overlayed with the Diffusion of Innovation model and considered the extended theory of the Crossing the Chasm to help identify barriers to the adoption of internet-based tools.

The analysis has identified the difficulty that consumers and businesses are having navigating rural, regional and remote internet connectivity. It has established a baseline understanding of a new phenomenon identified as 'Connectivity Literacy' (understanding how to get and stay connected), which is a pre-cursor to Digital Literacy (understanding how to use different devices, software, and operating systems).

Understanding and applying the concept of Connectivity Literacy provides the opportunity to build critical mass around internet connectivity knowledge and understanding that can advance adoption and innovation in rural, regional and remote areas.

Introduction

Access to internet connectivity in RRR areas of Australia has improved in the past four years (Australian Government, 2020, 2021, 2022, 2023). However, for many people and businesses living in RRR areas, the ability to get connected, stay connected and use that connection remains difficult. Previously, a lack of connectivity in RRR areas has been attributed to a lack of access, expense, education level, available infrastructure and policy and operations (Curtin, 2001; Freeman & Park, 2015; Park et al., 2019; Salemink et al., 2017). However, as newer technologies and a greater choice in RRR connectivity emerges, a lack of connectivity success can also be attributed to an individual's level of connectivity ability (Deursen & van Dijk, 2010; Park et al., 2019). Whilst connectivity literacy plays a large role in the success of getting connected and staying connected, other barriers to connectivity such as adequacy, affordability, consumer guarantees, redundancy and reliability also factor into connectivity problems in regional telecommunications, all of which underpin the need for sound connectivity literacy.

Connectivity Literacy (understanding how to get and stay connected) focuses on the knowledge needed to access telecommunications services, particularly broadband and voice, which includes understanding available technologies, navigating provider options, selecting appropriate plans, and managing equipment. It addresses the practical aspects of getting connected and staying connected, including the factors that affect connectivity quality and availability. Digital Literacy (Gilster, 1997; Heitin, 2016) (understanding different types of hardware, software, and operating systems) assumes a person already has access to reliable internet and emphasises their skills to effectively use digital tools and platforms. It involves the ability to operate devices, navigate software, and engage with digital content, fostering safe and productive digital interactions. It is measured by frameworks like the Australian Digital Inclusion Index (ADII, 2021), which evaluates digital inclusion through access, affordability, and digital ability. As shown in Figure 1, Connectivity Literacy is a precursor to Digital Literacy and a barrier to digital participation.

Figure 1: Connectivity Literacy is a precursor to Digital Literacy

Due to the complexity of using digital connectivity technologies in RRR areas, residents are having to develop new types of knowledge and skills that those in major cities do not have to acquire (Park et al., 2019). This includes knowledge of the numerous technologies available, including infrastructure and devices such as cellular booster, antennas, towers, and repeaters, as well as service plans (Park et al., 2019). However, it is often more difficult for regional Australians to obtain this knowledge (Szeles, 2018), as there is a limited amount of 'on the ground' understanding and independent advice about telecommunications infrastructure that can be used in RRR properties and communities.

Methods

Secondary data research (Manu et al., 2021) allowed the researchers to leverage pre-existing data that was originally collected to examine telecommunications delivery and how the internet was used and understood by women, farmers and small to medium enterprises in rural, regional and remote regions across Australia. Secondary data selected was appropriate because it was relevant to both the population and the phenomenon under study (Silver & Wrenn, 2013), allowing the researchers to derive conclusions about Connectivity Literacy. Thematic analysis (Lyons & Coyle, 2021) was used to identify, analyse and interpret people's views, opinions, knowledge, experiences, or values to derive patterns of meaning (Belotto, 2018) within the qualitative data that supported conclusions aligned to connectivity literacy.

Secondary data sets from three academic mixed methods (Creamer, 2017) research projects provided quantitative and qualitative data (online surveys N=625; focus groups N=27) for analysis (Harrington, 2024; Hay, 2018b; Wilson, 2022). Secondary data from three large consumer surveys (N=4180) (Hay, 2016, 2017, 2018a) were also analysed. In addition, submissions from the past 10 years to government enquiries into regional telecommunications containing lived experience case studies were also included in the analysis (Australian Government, 2008, 2012, 2015, 2018; Glasson et al., 2008; Hartsuyker et al., 2021; McKenzie, 2018, 2021; Shiff et al., 2015; Sinclair et al., 2012; Single et al., 2024; Sparrow, 2015, 2018; Stretton et al., 2021). The final data set was drawn from posts on the Better Internet for Rural Regional and Remote Australia Facebook page, which started in 2014 with approx. 500 members and in 2024 has almost 16,000 members (BIRRR., 2014).

Findings were overlayed with the Diffusion of Innovation Model (Rogers, 2003) and Moore's Chasm (2014), as shown in Figure 2. Rogers (2003) describes how practices spread over time ultimately lead to adoption and Moore (2014) identified a gap between early adopters and the early majority that contain critical barriers to adoption. The findings demonstrate how poor Connectivity Literacy is a barrier to the adoption of internet-based tools.

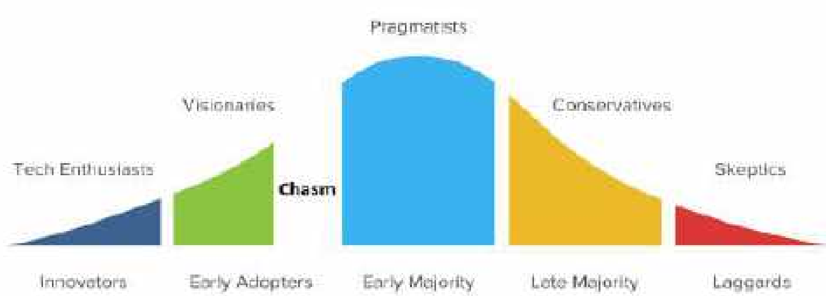

Figure 2: Moore's Revised Diffusion of Innovation Model (2014)

Results

Connectivity Literacy

The data demonstrated that Connectivity Literacy affects all types of consumers and is not limited by education, culture or age, Table 1.

Table 1: Connectivity Literacy Indicators

Topic		The Chasm	Diffusion/Dis-Adoption		
Innovators	Early Adopters	Critical Barriers to Adoption	Early Majority	Late Majority	Laggards
Connectivity Literacy – All the things a consumer needs to know to get connected and stay connected to the internet		How to choose a technology, provider, plan, choosing & installing equipment, troubleshooting a connection, staying connected in an emergency and where to go to get help.	• Mums / Dads / Children / Young Adults • Workers / Volunteers / Business Owners • First Nations / Different Cultural Backgrounds • Government (local, state, federal) • Researchers /All Education Levels • Young / Old		

Functional Literacy

Literacy is traditionally defined as the ability to read, write, and perform basic arithmetic. However, functional literacy extends beyond these basic skills to include the practical application of reading, writing, and math in real-life situations (Nutbeam, 2008). Functional literacy encompasses the ability to understand and use information effectively for daily tasks, such as interpreting graphs, managing finances, and making informed decisions. This broader definition highlights the importance of skills like media literacy, financial literacy, and health literacy, which are essential for navigating today's complex, high-tech society. While basic literacy is foundational, functional literacy ensures individuals can actively participate and thrive in their communities. In 2001, the Australian Council for Adult Literacy (2001) identified that one in five adults do not have the functional literacy skills to effectively participate in everyday life. In addition, the Australian Bureau of Statistics (2011-2012) identified that only 3% of Australians have the ability to use digital technology, communication tools and networks beyond basic applications such as email and web browsing. The data highlighted functional literacy as a foundation for digital inclusion and its impact on connectivity adoption outcomes, see Table 2.

Table 2: Functional Literacy Indicators

Topic		The Chasm	Diffusion/Dis-Adoption		
Innovators	Early Adopters	Critical Barriers to Adoption	Early Majority	Late Majority	Laggards
Functional Literacy - encompasses the ability to understand and use information effectively for daily tasks, such as interpreting graphs, managing finances, and making informed decisions (Nutbeam, 2008)		• Lack of practical skill set needed to get connected and stay connected to equitable, affordable and reliable voice and broadband services • Inability to function effectively online • Insufficient functional literacy, which is a core foundation to digital inclusion	• 44% stay with provider that does not meet their needs • 63% prevention from adopting new technology • 70% negative impact on business operations • 57% negative impact on productivity • 37% negative impact on customer service "makes me look unreliable" • 48% have not changed their provider in the past 3 years • High transactional costs: administrative time, time to learn new technology, troubleshoot issues		

Digital Apathy and Misinformation

The data shows that consumers are experiencing digital apathy caused by various factors including fear of the unknown, a lack of exposure or experience with technology, lack of time or a reluctance to change or try new things. A state of digital apathy can also be caused by people trying their best to solve their connectivity problems and 'giving up' as it becomes too difficult and takes too much time. Adding to digital apathy, widespread misinformation is often confusing, disruptive and causes consumer fatigue and frustration. Digital apathy makes it incredibly difficult to engage consumers including RRR users, industry, government, media, and researchers in understanding how to get connected and stay connected. The data highlights digital apathy and misinformation as significant barriers to connectivity adoption, as summarised in Table 3.

Table 3: Digital Apathy and Misinformation Indicators

Topic		The Chasm	Diffusion/Dis-Adoption		
Innovators	Early Adopters	Critical Barriers to Adoption	Early Majority	Late Majority	Laggards
Digital Apathy - an indifference or a deliberate lack of enthusiasm or interest towards digital technologies such as the internet, smart phones, computers, and other digital devices, that results in a genuine fatigue towards technology		• Lack of experience and exposure • Fear of the unknown • Negative messages from the bush grapevine, social media, the media • Negative past experience • Consumer fatigue/Cognitive overload • Inertia (tendency to do nothing) and status quo bias • Historical RSP practices	• "BUT there is only one provider, nothing else to choose from" • "Current plan restricted by sky muster" • "Don't think there are any other options" • "I don't know if I am locked in" • "I think we have just changed by default" • "There's no choice in what I can compare to as I really have one plan to choose from" • "We were waiting for Starlink to arrive, no other alternatives" • "I can't get NBN, I live remotely"		
Misinformation - false, inaccurate or misleading information; and **Disinformation** - information that is covertly spread deliberately to deceive or influence (O'Connor & Weatherall, 2019)		• Lack of dedicated rural regional and remote tech support • Lack of independent advice • Myths and furphies • Industry is profit driven not results driven • Industry undermined by scammers and misleading and deceptive practices, creating distrust	• Consumer confusion/mental burden • Consumer fatigue and frustration • Geographical narcissism "People in cities think what we do is less valid" • Lack of understanding from urban stakeholders – "if you're not happy why don't you move [to town]" • Constant change is disruptive and creates further barriers		

Discussion

Telecommunications have become an essential service, yet unlike other utilities (e.g., water, power) RRR consumers are expected to be intricately involved in the complexity of installation, delivery, and success of that service. Consumers lack personal resources and understanding to compare and match available technologies to their broadband and voice needs resulting in Connectivity Literacy issues. Poor connectivity literacy creates barriers for RRR consumers to get connected and stay connected resulting in negative experiences with technology that are difficult to overcome resulting in digital apathy causing people to give up, and ultimately to put up with substandard connections and ongoing issues. This is not only a significant safety concern but also creates lost productivity, affects education and mental health, and exacerbates social isolation for remote consumers.

A vast amount of industry and academic adoption literature fails to recognise functional connectivity literacy (getting connected and staying connected) as a precursor to digital literacy (using your connectivity) as a barrier to adoption. While connectivity infrastructure has considerably improved access over the past four years, it has resulted in a confusing landscape of connectivity options. There are also misconceptions about the availability of national broadband (nbn) services and alternative suppliers. To increase adoption of internet-based tools, health and education resources and land/animal business management tools, consumers need support to navigate and utilise the connectivity landscape that provisions internet access

(Get Connected) to troubleshoot their connectivity (Stay Connected) and to support adoption of internet-based tools (Use Connectivity).

Acknowledgements
Acknowledgement is given to the volunteer organisations who work tirelessly to gather information that supports the development of the new phenomenon of connectivity literacy. Volunteers are supported by James Cook University whose in-kind contributions ensures that this important work can be achieved.

Factors influencing adoption and sustained use of agricultural technology in grazing systems of Central Queensland

Barker, J[1]; Trotter, MG[1]; Williams, TM[1]

[1] Institute for Future Farming Systems, Central Queensland University, Rockhampton, Australia

Key words: AgTech, Adoption, Grazing, Producer, Perceptions

Abstract

Agricultural technology (AgTech) offers significant opportunities for enhancing productivity and sustainability in rangeland grazing systems; however, its adoption to date has been limited. This study examines factors influencing the adoption and sustained use AgTech among Central Queensland beef producers. Through semi-structured interviews with 15 beef graziers, we explore how producers' motivations, experiences, and perceptions affect their engagement with AgTech. Thematic analysis illustrates that adoption and continued use of AgTech are more likely when it enhances a producer's feelings of competence, is positively regarded by peers, and is considered a viable financial investment. Conversely, challenges in these areas often lead to low implementation or discontinuation. These insights can inform strategies to improve AgTech development and integration, ultimately enhancing the resilience and sustainability of extensive grazing systems.

Introduction

The agricultural sector is undergoing a transformative shift with the integration of advanced technologies, collectively known as agricultural technology (AgTech). These innovations aim to improve productivity, efficiency, and sustainability in farming practices (Rose & Chilvers, 2018). In beef grazing systems, AgTech offers tools for enhanced herd management, pasture monitoring, and resource optimisation. Technologies such as remote sensing, GPS tracking, and automated feeding systems have the potential to revolutionise traditional operations (Bailey et al., 2021). Although these represent advanced applications of AgTech, integration into beef businesses can be through much more conventional forms, such as the addition of weigh scale, or farm management software.

Despite the potential benefits, the adoption and sustained use of AgTech among beef producers varies widely. Some producers successfully integrate these technologies into their long-term operations, while others discontinue use after initial adoption (Fielke et al., 2020). Understanding factors influencing uptake and continued use is crucial for developing strategies to enhance sustained technology use if we are to increase productivity and resilience in the agricultural industry. Previous research has identified barriers such as high initial costs, lack of technical support, and integration difficulties with existing systems (Pierpaoli et al., 2013).

Incorporating agricultural extension methods tailored to diverse adoption pathways is essential for addressing these challenges. Recent research by Nettle et al. (2024) emphasises that effective extension requires addressing social, technical, and institutional barriers. Their findings highlight that a combination of peer learning, co-innovation, and tailored advice is critical for supporting producers through the adoption and continued use of technologies. This aligns with the focus of this study on understanding the roles of competence, community and financial risk perception in AgTech adoption, particularly as they influence producers' decisions to sustain or discontinue the use of these tools.

Methods

A qualitative research design was employed to explore the motivations, experiences, and perceptions of beef graziers regarding AgTech adoption and continued use (approval number: 24-883). A phenomenological approach facilitated an in-depth understanding of the lived experiences of producers and their involvement with AgTech (Creswell & Poth, 2018). Participants were selected using random purposeful sampling, targeting Central Queensland beef graziers. Inclusion criteria required active involvement in beef grazing operations, and willingness to discuss their experiences with Agtech. Recruitment occurred through industry networks and producer associations. A total of 15 beef graziers participated, representing diverse enterprise sizes, and levels of AgTech engagement. Semi-structured interviews were conducted either face-to-face, or via telephone. An interview guide was developed, covering topics such as business background, motivations for AgTech adoption, experiences with implementation, perceptions of usability and usefulness, and factors influencing continued use or discontinuation. With consent, interviews were audio-recorded and transcribed verbatim. Thematic analysis was conducted following the guidelines outlined by Braun and Clarke (2006). NVivo 12 software facilitated the coding and identification of patterns in the data. Initial codes were generated inductively. Themes were iteratively refined to improve accuracy and distinctness.

Results

A total of 15 interviews were conducted with six males, six females and three couples. All participants held an active role in decision making on property either through management roles or ownership. The length of interviews ranged from 15 to 120 minutes, resulting in approximately 24 hours of recorded conversations. Ten participant's businesses were primarily involved in cattle breeding and growing. Three participants had mixed farming operations with beef cattle alongside cropping enterprises. One participant had a sole focus on backgrounding and trading cattle, and one business operated as a stud. The number of cattle in each business ranged from 120 to 6,500 head.

Three primary themes emerged from the analysis that influence adoption and continued or discontinued use of AgTech: Competence, Community, and Perceived financial risk.

Competence

The theme of competence explores how the Agtech tool contributes to producer's feeling capable within their business. This emerged as a critical factor influencing both adoption and sustained use of technology.

<u>Usefulness with regard to business priorities:</u> Beef cattle businesses vary in their structure, focus and measures of success. A producer's perspective of a tool being useful varies depending on their priorities. In this study, usefulness was commonly identified through operational benefits such as labour saving, increased confidence in decision making and improved communication. Discontinuation was prevalent where the tool was not seen to add value to a producers existing skillset or where it imposed on a higher

priority value, for example doing things quickly. One producer had AgTech installed (EID's in every animal, an EID scanner and a set of scales) however indicated:

"I just don't use it because it's quicker without it. It stays slow with it. Like lots of places and that – you go through, and you watch them and they're stuffing around. And they're read this one, this one doesn't read so they've got to run it back and pull the tag out. Where I can pump them straight through in an hour."

Usability and adaptation to local conditions: The usability of AgTech tools and their adaptability to individual contexts significantly impacted producers' sense of competence. Tools that were intuitive, required minimal training and offered practical ways to maintain the system, enhanced confidence and encouraged continued use. Whereas technologies that were perceived as complicated or not suited to the producers' operating environment diminished competence, often resulting in discontinuation.

"It won't actually sync in the paddock without losing data. So then, well then you lose your confidence in the program, right? Then you've got to come back to the office and it's another job you've got to sit down and do. Whereas if you're in the paddock and you're moving them that was one of the prime draw cards to using it."

Access to training and support: Adequate training and technical support contributed to producers feeling competent and more capable in using the Agtech tools to benefit their business. Initially being connected to a person directly for follow up support was highly regarded. Often, once producers had confidence that they were supported, they were more inclined to troubleshoot on their own and successfully navigate implementation phases. An absence of support from some AgTech providers was linked to frustrations, reduced confidence and discontinuation.

Community

The theme of community encompasses the social and relational factors influencing AgTech adoption and sustained use. Producers valued acceptance within their community and were cautious about deviating from accepted norms.

Peer influence and social proof: Producers were curious about, and strongly influenced by, the experiences and opinions of their peers. Observing successful use of AgTech by peers increased confidence and motivation to explore using technology. They often sought reassurance from trusted community members before fully committing to AgTech use.

"Your next door neighbour or your cousin's uncle who has been using it for two years, or you know whatever they've all got experience. So, um, to me I would go to someone who I know has used it."

Collaborative learning and support networks: Community networks provided opportunities for shared learning and support. Often key producers were referred to as they had a reputation for being a trusted source for ground-truthed Agtech experience. Engagement with peers facilitated knowledge exchange, problem-solving, and mutual support. Producers without access to supportive networks were more comfortable with 'business as usual' which hindered exploration and sustained use of AgTech.

"Person 1 is trying to make you use that other shit. Yeah, but I don't want to use it. What happens if your phone goes flat or something? … I don't think many people do use the electric one."

Perceived financial risk
Producers highlighted several dimensions of financial risk associated with AgriTech adoption, reflecting concerns about return on investment, reliability, and economic justification.

Uncertainty around lifespan and reliability: AgTech tools were often perceived as high-risk investments due to uncertainties around their lifespan and reliability. Producers expressed frustration when tools failed to operate consistently. Others relayed experiences with discontinued technology and tools that didn't meet the expectations set. Malfunctions disrupted operations, incurred added labour and maintenance expense and eroded confidence in the technology's value.

"It's just that it's got a few hiccups that can be a pain in the butt sometimes, and I'll go down there, and I'll start a new session and it'll just throw me a curveball. And I've got to work it out, and, you know what it's like. You've got people waiting around."

Challenges in evaluating return on investment and cash flow constraints: Many producers struggled to assess the financial value proposition of AgTech tools. The economic benefits often required long-term use to materialise, while the upfront costs presented immediate challenges.

"The problem is, the case has to be so compelling because if it's not you constantly think, 'What else could I buy for that?' And we just get away with doing it."

Prioritisation of tangible benefits**:** Technologies with clear and direct economic benefits, such as preventing theft, were prioritised over other AgTech tools. Producers felt more confident investing in tools with demonstrable short-term outcomes, which contrasted with the abstract or delayed benefits of many AgTech solutions.

"Technology's not, it's important but it's not of great importance to us I guess you'd say. You know, our security cameras and stuff like that yeah that's important because we need to be able to monitor that no one's driving in and stealing all of our diesel"

Discussion and Conclusion
This study highlights the complex factors influencing the adoption and sustained use of AgTech among beef producers in Central Queensland, emphasising the importance of tailoring solutions to individual business priorities. Adoption is driven not only by technological capabilities but also by human behaviour, social dynamics, and the specific contexts of each enterprise. Technologies that enhance producers' feelings of competence, align with their priorities, and address their needs for usability and reliability are more likely to be adopted and used long-term.

Competence emerged as a critical theme, with producers favouring tools that are intuitive, adaptable to local conditions, and supported by training. This aligns with findings by Sewell et al. (2017), who highlight that competence-building through training and tailored advice is essential for successful technology adoption. Conversely, technologies perceived as unreliable or difficult to use often led to frustration and discontinuation. Community influence also plays a vital role, as producers rely on peers and trusted individuals to validate their decisions. As suggested by Prager and Creaney (2017), peer-to-peer networks and social learning environments can build confidence in adopting new technologies. Stories and experiences shared by relatable figures can build confidence and foster adoption, while negative perceptions can hinder uptake.

Perceived financial risk remains a significant barrier, with producers expressing difficulty in assessing the return on investment for many AgTech tools. Immediate and tangible benefits, such as those provided by security systems, were prioritised over tools with long-term or less visible payoffs. Clear communication about economic benefits, supported by cost-benefit analyses and evidence of success in local contexts, can help address these concerns.

The adoption of AgTech requires a process of change that often involves vulnerability and habit shifts. Extension strategies should acknowledge this, providing time, support, and accountability mechanisms to facilitate the transition. Timing is also crucial, with producers more likely to adopt new tools when triggered by specific events or compelling evidence of benefit from trusted sources.

Although the sample size of this study is small, the diversity of experiences underscores the need for a tailored approach to AgTech adoption. Strategies should prioritise building competence, leveraging community networks, addressing financial concerns, and supporting producers throughout the adoption process. By focusing on shared lived experiences and aligning with producers' values and goals, AgTech adoption can be enhanced, contributing to more resilient and sustainable grazing systems.

Long-term chemical management of undesirable brush on southwestern U.S. rangelands

Medlin, CR[1]

[1] Environmental Science U.S., LLC, 5000 CentreGreen Way, Suite 400, Cary, NC 27513, case.medlin@envu.com

Key words: rangeland restoration; woody plant control; aminocyclopyrachlor; *Prosopis glandulosa*; *Acacia schaffneri*

Abstract

Woody plant encroachment on rangeland used for beef cattle production and/or wildlife use in the southwestern United States has been a major problem of ranchers for many decades. Aminocyclopyrachlor premixed with triclopyr-amine was first marketed for use on grazing lands in Texas, Oklahoma, New Mexico, and Arizona in 2020. This herbicide was marketed for control of honey mesquite (*Prosopis glandulosa*) (NRCS 2025), huisache (*Vachellia farnesiana* a.k.a. *Acacia farnesiana*), and associated brush species and broadleaf forbs on grazing lands. Long-term (i.e. four to ten years post-application) honey mesquite canopy evaluations in aerial and ground broadcast-applied trials revealed more than twice the treatment life (i.e. the time from treatment until brush canopy returns to an economic threshold) with aminocyclopyrachlor+triclopyr-amine (ACP+T) treated plots versus plots treated with past industry standards (Medlin et al. 2019). Similar results were obtained for huisache treated plots evaluated four to six years post-application. Recent research has evaluated picloram and/or chlorsulfuron+metsulfuron-methyl combinations applied with ACP+T to widen the spectrum of activity and address additional undesirable species on rangelands while evaluating impacts on desirable plant species. When evaluated 40 months after application, ACP+T (140+280 g ae ha^{-1}) applied alone was highly efficacious (100% mortality) on honey mesquite, moderately efficacious (66% mortality) on guajillo (*Acacia berlandieri*), and slightly efficacious (less than 25% mortality) on all other woody plant species present. When ACP+T was applied in combination with picloram (560 g ae ha^{-1}) or picloram and chlorsulfuron+metsulfuron-methyl (10.5+33.5 g ai ha^{-1}) mortality of twisted acacia (*Vachellia schaffneri* a.k.a. *Acacia schaffneri*) increased to 25% and 50%, respectively. A tank mix of ACP+T (210+420 g ha^{-1}) with chlorsulfuron+metsulfuron-methyl resulted in 100% mortality of honey mesquite, twisted acacia, and whitebrush (*Aloysia gratissima*), less than 25% mortality of spiny hackberry (*Celtis ehrenbergiana*), and 0% mortality of ephedra (*Ephedra antisyphilitica*), guayacan (*Guaiacum angustifolium*), and lotebush (*Ziziphus obtusifolia*).

Introduction
Woody plant encroachment across southwestern United States' rangeland has reduced soil and surface water availability, forage production, diversity of desirable native forbs, livestock carrying capacity, livestock management efficiency, and wildlife habitat, while it has increased degradation of infrastructure (e.g. fences) and rangeland management costs (Allred 1949; Boggie et al. 2017; Dahl et al. 1978; Fisher 1950; Laxson et al. 1997; Smith and Rechenthin 1964; Teague et al. 1997, 2008; Thurow et al. 2000; Timmer et al. 2014). Although chemical and mechanical management options have been implemented for over five decades, woody plant encroachment on rangelands has continued to escalate. For example, the USDA Soil Conservation Service (USDA-SCS) estimated in 1963, 35.8 million hectares of Texas rangeland had been invaded by woody plants (USDA-SCS 1963). The infestation increased to 37.2 million hectares by 1973 (USDA-SCS 1973) and to 42.7 million hectares by 1985 (USDA-SCS 1985), while over 12 million hectares received treatment during that time span.

Some of the major species comprising this undesirable woody plant invasion include honey mesquite, huisache, whitebrush, tarbrush (*Flourensia cernua*), and catclaw acacia (*Senegalia greggii* a.k.a. *Acacia greggii*), however, not all woody plants on southwestern U.S. rangelands are undesirable. To complicate matters, the undesirable woody plants are typically found growing in association with desirable woody species such as hackberry (*Celtis laevigata var. reticulata*), lotebush, guayacan, etc. The close association of desirable and undesirable plants on rangeland make selective application to undesirable plants impossible with broadcast applications.

Medlin et al. (2019) reported broadcast-applied aminocyclopyrachlor+triclopyr-amine (ACP+T) more effectively killed honey mesquite and huisache, reduced the plant canopies of these species, and extended the treatment life compared to previous industry standard treatments. The research focused on long-term control of honey mesquite and huisache only, did not address other undesirable woody species, and did not include impacts on associated desirable species. Therefore, the objective of this research was to evaluate ACP+T applied alone or with chlorsulfuron+metsulfuron-methyl, and/or picloram for management of honey mesquite, whitebrush, twisted acacia, and other undesirable woody plants as well as the impacts of these treatments on desirable woody plant species.

Methods
A trial was established on a privately-owned ranch in Duval County, Texas. Individual plot dimensions were 180 m by 1300 m. Treatments were applied June 18, 2021, with fixed-wing aerial application equipment to mixed woody plant stands of actively growing brush canopies with healthy vegetation. Treatments consisted of ACP+T (140+280 g ae ha^{-1}) applied alone, with picloram (560 g ae ha^{-1}), with picloram (560 g ha^{-1}) and chlorsulfuron+metsulfuron-methyl (10.5+33.5 g ai ha^{-1}), and ACP+T (210+420 g ha^{-1}) with chlorsulfuron+metsulfuron-methyl (10.5+33.5 g ha^{-1}). All treatments were applied in 45 l ha^{-1} water carrier with 365 ml ha^{-1} methylated seed oil / organosilicone adjuvant.

Mortality assessments by species were collected 16 and 40 months after treatment. Plants were considered dead if no green vegetation was present in the leaves or stems.

Results
All treatments killed honey mesquite 100% when evaluated 40 months after application (Table 1). ACP+T applied at 140+280 g ha^{-1} killed less than 25% of the twisted acacia population and 0% of the whitebrush plants present. When this treatment was tank mixed with picloram, twisted acacia mortality increased to 50% but there was no change in the whitebrush mortality. ACP+T at 210+420 g ha^{-1} and applied with

chlorsulfuron+metsulfuron-methyl resulted in 100% mortality of honey mesquite, twisted acacia and whitebrush.

ACP+T applied at 140+280 g ha^{-1} killed 66% of the guajillo population present and 93% when applied with 560 g ha^{-1} picloram. All other traditionally accepted wildlife beneficial woody plants present suffered less than 25% mortality when ACP+T was applied alone or in a tank mix with picloram or chlorsulfuron+metsulfuron-methyl. However, when ACP+T was applied with picloram and chlorsulfuron+metsulfuron-methyl guajillo and spiny hackberry resulted in 57% and 71% plant death. The other desirable woody plants present (i.e. ephedra, guayacan, and lotebush) did not suffer significant plant losses regardless of herbicide treatment or rate.

Table 1. Three years after treatment mortality ratings (%) of woody plant species resulting from ACP+T applied alone or with picloram and/or chlorsulfuron+metsulfuron-methyl tank mix partners sprayed June 18, 2021, on a ranch in Duval County Texas.

		Aminocyclopyrachlor + Triclopyr-amine (g ae + g ae ha^{-1})[1]			
		(140 + 280)			(210 + 420)
		Tank Mix Partner (g ae or g ai ha^{-1})[1]			
		None	Picloram (560)	Picloram + Chlorsulfuron + Metsulfuron (560 + 10.5 + 33.5)	Chlorsulfuron + Metsulfuron (10.5 + 33.5)
Common name	**Latin name**	Mortality (%)			
Traditionally Undesirable Plants					
Honey mesquite	*Prosopis glandulosa*	100	100	100	100
Twisted acacia	*Acacia schaffneri*	21	50	25	100
Whitebrush	*Aloysia gratissima*	0	0	--[2]	100
Traditionally Wildlife Desirable Plants					
Ephedra	*Ephedra sp.*	0	0	0	0
Guajillo	*Acacia berlandieri*	66	93	57	--[2]
Guayacan	*Guaiacum angustifolium*	0	0	0	0
Lotebush	*Ziziphus obtusifolia*	17	0	0	0
Spiny hackberry	*Celtis ehrenbergiana*	0	3	71	23

[1] For rate calculations, g ae (acid equivalent) was used for aminocyclopyrachlor, triclopyr-amine, and picloram and g ai (active ingredient) was used for chlorsulfuron and metsulfuron.

[2] Population was insufficient for assessment.

Discussion

Late spring through summer is the recommended application time for ACP+T when targeting mesquite species (*Prosopis* spp.) across Texas while fall applications of ACP+T are most suited for huisache. Species' efficacies with ACP+T are best when applications are made during the corresponding season. This trial was sprayed mid-summer of 2021 during the recommended mesquite application window. This may explain the resulting high mortality of ACP+T applied alone on honey mesquite and its limited impact on twisted acacia, a closely related species to huisache.

ACP+T is highly effective for control of several problematic leguminous species including, honey mesquite, huisache, honey locust (*Gleditsia triacanthos*), *Lespedeza* spp., etc., but has limited impact on other non-leguminous species such as hackberry, lotebush, oaks (*Quercus spp.*) and other desirable species. This is advantageous for land managers whose goals include more diverse plant communities, e.g. wildlife habitat management. For these land management models ACP+T applied alone has a good fit for its limited impact on many desirable wildlife browse and wildlife-positive habitat species such as lotebush, ephedra, spiny hackberry, and guayacan. However, when land managers' goals are more grazing land focused for domestic livestock, ACP+T alone may leave too many woody plant species to compete with desirable grasses and forbs. In these instances, tank mixtures with other herbicides such as picloram, chlorsulfuron+metsulfuron-methyl, etc. can expand the spectrum of activity and help to transform the land to closer meet the landowner's goals.

Greenhouse gas mitigation strategies in East African pastoral systems: beyond technical solutions

Ash, R[1]; Höglund-Isaksson, L[2]

[1] The University of Tasmania, Tasmania, Australia; [2] International Institute for Applied Systems Analysis

Key words: pastoralism; methane; climate

Abstract

Prioritizing the support of pastoralists in Kenya through a bottom-up approach, this study focuses on identifying strategies to enhance their livelihoods, with subsequent evaluation of the impact on greenhouse gas emissions. Using the Greenhouse Gas and Air Pollution Interactions and Synergies (GAINS) model and Tier 2 emissions factors, we develop a region-specific emissions inventory and evaluate how supporting pastoralist livelihoods intersect with emissions mitigation. Pastoralism, vital for local economies and ecosystems, has often been misrepresented in climate policy due to the application of industrial-focused emission reduction strategies that do not fit these extensive systems. Our research identifies effective interventions, both institutional and technical, to support pastoralist livelihoods while addressing climate change. Institutional strategies include enhancing public health and education, improving early warning systems, leveraging social capital, and promoting mobility, each of which contributes to resilience and adaptation but requires further exploration of their emissions impacts. Technical measures, such as fodder harvest and storage and disease prevention through vaccination, are shown to reduce enteric fermentation emissions by 22% within pastoral systems. The study emphasizes the need for tailored climate policies that incorporate traditional practices and support pastoral systems effectively, advocating for a holistic approach to emissions reduction that respects and enhances local knowledge and practices.

Introduction

Pastoralism, in particular, has been a silenced perspective in the policy debate (Houzer & Scoones, 2021). Pastoralists are livestock keepers managing cattle, goats, sheep, camels, llamas, yaks, reindeer and other animals on extensive rangelands covering over half of the world's land surface and supports millions of people's livelihoods (ILRI et al., 2021). These extensive livestock systems occur where alternative forms of agriculture do not exist and play a crucial role in providing nutrition to often poor and marginalised populations (Iannotti et al., 2021; Scoones, 2021). Traditional indigenous knowledge is used amongst communities to provide ecosystem services while adapting to variable climates (FAO, 2024). Despite the opportunities offered by pastoralism, their needs in climate change mitigation and adaptation policy have often been neglected (Adesogan et al., 2020; Harrison et al., 2021). A more nuanced, balanced discussion of livestock sustainability is needed to address this inequality and can only be achieved with more specific research focusing on these regions (Hallström et al., 2015; Johnsen et al., 2019; Nordhagen et al., 2020; Paul et al., 2021).

Previous research has demonstrated that technical emissions abatement solutions typically used in industralised systems, such as breed and feed optimisation, are not applicable to pastoralists in Africa due to differing priorities (Cheng et al., 2022; Höglund-Isaksson et al., 2020; Houzer & Scoones, 2021). Rather than productivity as a core focus, indigenous breeds and management systems are crucial in supporting cultural practices, nutritional security and risk management as well as providing low emissions per head. Instead, emissions are more closely linked to underpinning institutional factors (Reid et al., 2004). As of current, limited research exists that uses a transdisciplinary approach to identify strategies that support pastoralists in Africa from the bottom-up in climate adaptation while also examining the associated emissions.

Supporting pastoralism in the context of drylands in East Africa while considering emissions is a '*wicked problem*' that requires a transdisciplinary approach introducing complexity (Lawrence et al., 2022). Leveraging the Greenhouse Gas and Air Pollution Interactions and Synergies (GAINS) model from International Institute for Applied Systems Analysis (IIASA), this research aims to provide nuanced insights into region-specific strategies that align with the diverse pastoralist systems, cultural practices, and dietary patterns of East Africa. Drawing on local knowledge from bottom-up social science research (Ash et al., 2024) focused on climate adaptation amongst pastoralists in East Africa, strategies that support livelihoods in climate adaptation are identified.

Methods

Emissions Estimation

The GAINS model estimates emissions bottom-up, i.e., quantifications of human activities contributing to emissions are multiplied by an emission factor representing the average emissions per unit of activity. This research builds upon existing Tier 1 national inventories of methane (CH_4) emissions from enteric fermentation in livestock systems in Kenya (Höglund-Isaksson et al., 2020) by using country-specific information to allow for deriving country- and sector/technology- specific emission factors at a Tier 2 level. CH_4 emissions are estimated for enteric fermentation emissions in livestock systems in Kenya spanning a timeframe from 1990 to 2050 in five-year intervals.

Following the general GAINS methodology (Amann et al., 2011), emissions from source *s* in region *i* and year *t* are calculated as the activity data A_{its} times an emission factor ef_{ism}. If emissions are controlled through implementation of technology *m*, the fraction of the activity controlled is specified by $Appl_{itsm}$, i.e.,

$$E_{its}=\sum m[A_{its}*ef_{ism}*Appl_{itsm}],$$

where

$$\sum mAppl_{its}=1,$$

and where A_{its} is the activity (number of animals)

ef_{ism} is the emission factor for the fraction of the activity subject to control by technology *m*,

$Appl_{itsm}$ is the application rate of technology *m* to activity *s*.

Hence, for each emission source sector, country-and year- specific sets of application rates for all the possible technologies (including no control) are defined such that application rates always sum to unity.

Systems Boundary
This study focuses on estimating CH_4 emissions from enteric fermentation of livestock, specifically cattle, sheep, goats, and camels in Kenya (Figure 1). The system boundary is defined to include only methane emissions arising from enteric fermentation processes in these animals. Other potential sources of emissions, such as:

- Methane and nitrous oxide emissions from manure management,
- Carbon sequestration from soils, trees, and plants, and
- Other greenhouse gas emissions from the agricultural sector,

are excluded from this analysis.

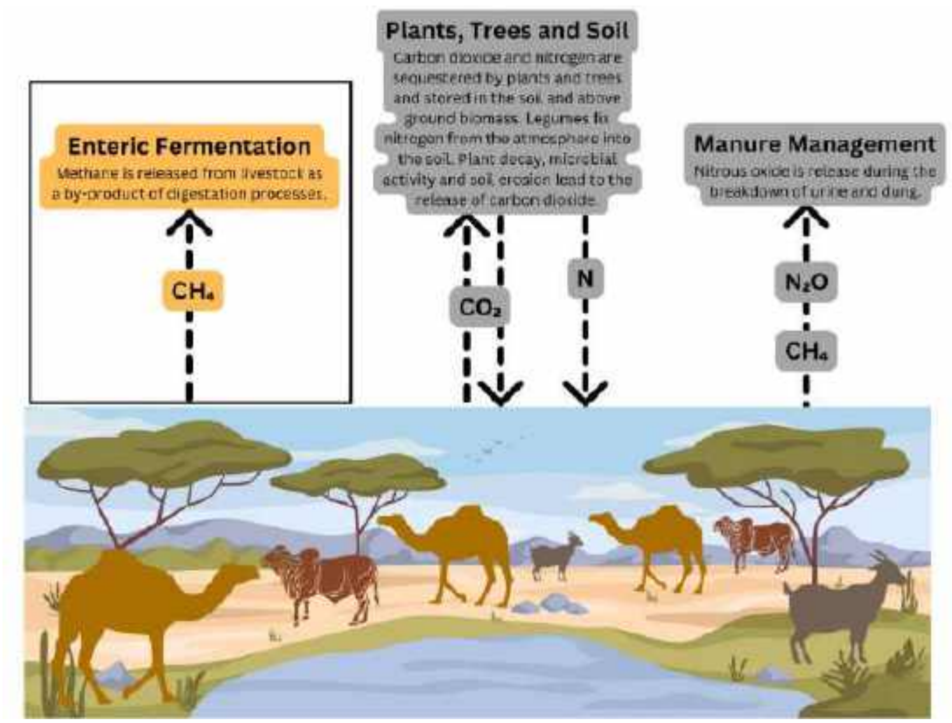

Figure 1: Emission sources and sinks in pastoral livestock systems including cattle, camel, sheep and goats. Enteric fermentation is highlighted as the focus of this study.

Emission Factors
Emission factors and calculation method (Tier 1 vs. Tier 2) for each sector used in the GAINS modelling are represented in Table 1.

Table 1: Description, emission factor and associated method and source of the sectors used in the GAINS methodology.

Animal Categories	Emission Factor Selection	Emission Factor	Method	Source
Pastoral camels	Tier II data unavailable for camels.	46	IPCC Tier I	IPCC (2006)
Pastoral sheep and goats	Aligned smallholder systems in Kenya.	4	Diet-based IPCC Tier II	Goopy et al. (2021)
Pastoral dairy cows	Smallholder dairy farm in central Kenya using local breeds and aligned milk production levels.	76.4	Diet-based IPCC Tier II	Wilkes et al. (2020)

Agropastoral dairy cows	Semi-zero grazing conditions mimicking agropastoral dairy production.	74	Diet-based IPCC Tier II	Wilkes et al. (2020)

Interventions

A number of institutional and technical interventions were assessed including: public health and education, anticipatory action, social capital, mobility, security, pasture enclosures, fodder harvest and storage, species diversification and disease prevention through vaccination. These interventions—whether institutional or technical—have varying impacts on pastoral livelihoods, climate resilience, human health, and food security. Each approach carries both benefits and challenges, which must be carefully balanced to ensure that pastoral systems can adapt effectively to climate change while preserving their cultural and economic importance.

On the basis of literature availability, two strategies were selected for further quantifications of impacts on methane emissions: fodder harvest and storage, and disease prevention (Table 2). While examining the impact of all interventions identified as a welfare package would be of great interest, the literature is not currently advanced enough to make these linkages. In addition, the inherent nature of pastoralism not being constant or linear, but rather adapting to variability, makes the prediction of stock flux variation due to intervention a challenge. However, both fodder harvest and storage as well as disease prevention pathways have a direct impact on methane emissions at the animal level and can therefore be modelled using the GAINS methodology.

Table 2: Interventions and their associated methane reduction mechanisms, removal efficiency (%) and sources.

Intervention	CH_4 Reduction Mechanism	Removal Efficiency (%)	Source
Fodder Harvest and Storage	Increased digestibility and reduced methanogen activity	5-20	(Adesogan et al., 2020; Beauchemin et al., 2011; Hristov et al., 2013)
Disease Prevention	Reduced mortality and replacement rates, improved feed conversion efficiency, reduced methane yield through gastrointestinal interactions	33	(Ezenwa et al., 2020; Fox et al., 2018)
Combination		45	As above.

Results and Discussion

Figure 2 represents that with implementation of disease control and improved fodder quality at a feasible adoption rate in pastoral systems, annual enteric fermentation CH_4 emissions in 2050 would be 22% less in pastoral systems and 11% less across all livestock systems compared to the BAU approach. This means Kenyan pastoralist systems would emit 3,406kt CH4 less between 2030 and 2050, nearly double the country's total annual CH_4 emissions in 2020 based on the recent GAINS modelling (Höglund-Isaksson et al., 2020).

Human population growth and increased demand for red meat and milk protein per capita to meet nutritional targets in Kenya underscore the unavoidable increase in emissions even with mitigation strategies. Despite the increase in absolute emissions, milk and red meat protein demand per capita in Africa will still remain 51% and 78% smaller, respectively, when compared to Europe in 2030 (Arndt et al., 2022). On the other hand, enteric CH_4 emissions per capita will be significantly higher than in Europe in 2030 due to the significantly higher emissions intensity of the systems in Africa. This disparity emphasizes the need for tailored approaches: reducing consumption in Europe may be effective for limiting emissions due to low emissions intensity but high demand in consumption, while in Africa, supporting livestock systems to meet nutritional needs while managing emissions is crucial. Understanding the drivers that create change are crucial for this process. The current literature tends to examine animal efficiency and productivity in isolation when discussing how to support pastoralists and climate (Henry et al., 2018; Krätli et al., 2013). However, previous research (Young, 2020) in the pastoral context has shown, for example, that there is no clear correlation between the immediate drivers of acute malnutrition, diet and disease, but rather, systemic and institutional factors such as livelihood systems, environmental aspects and gender relations. This research offers a region-specific perspective on integrating local context into strategies that balance livestock sustainability and climate goals.

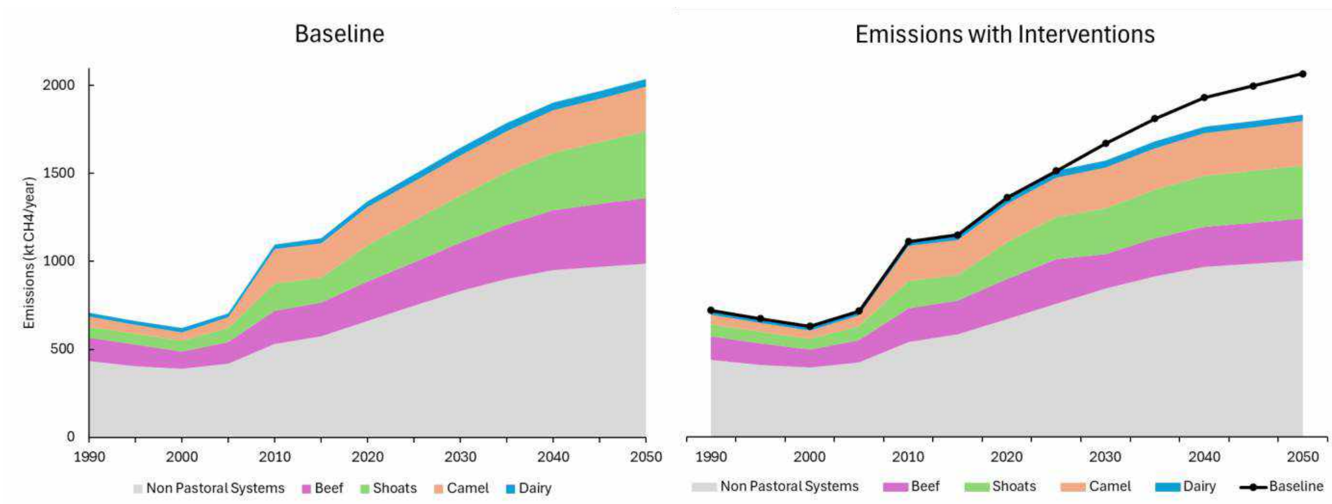

Figure 2: Enteric fermentation CH_4 emissions 1990–2050 in Kenya in the baseline scenario (left panel) and a feasible intervention scenario (right panel) with the enteric fermentation from non-pastoral systems represented in grey.

Information technologies to empower and support land managers to participate in carbon farming projects: a case study from Australia's rangelands

Ferguson, T[1]; Emms, J[1]

[1] Select Carbon, 275 George Street, Brisbane, QLD 4000, Australia

Key words: rangeland management; collaboration; farm data platforms; engagement.

Abstract
Information technologies can empower and promote active participation from land managers in carbon farming projects. As a carbon service provider, we have leveraged the capabilities of the information technology Fulcrum® to develop customised applications to support land managers undertaking Human Induced Regeneration (HIR) projects in remote rangeland environments. Through a shared platform, Fulcrum allows land managers and carbon service providers to record and share information on management interventions which promote carbon sequestration, vegetation growth and project progress. This approach can also enhance the integrity of HIR projects by using technological solutions to provide evidence of project activities and progress. In this study we look at the use of Fulcrum for the portfolio of HIR projects that we service in the southern rangelands of Western Australia (WA). We assess Key Performance Indicators (KPIs) for the database of the 'Management Activities Application' (MAA) which is the customised application that we created in Fulcrum to support these land managers. The results demonstrate the successful adoption and sustained use of Fulcrum by land managers in these locations with ongoing engagement and collaboration key contributors to this. The adoption and establishment of these ways of working provides opportunities to support land management in these areas more broadly.

Introduction
Carbon farming has become a prominent new land use in Australia's southern rangelands (Baumber et al. 2020). It presents a unique opportunity to support land managers in these areas to viably implement sustainable land management practices over the long term. Here we explore the role that information technology is playing in supporting land managers to participate in carbon farming opportunities through a case study of the portfolio of HIR projects that we service in the southern rangeland of WA. We also consider the broader opportunities to support land managers that this adoption and collaboration via information technologies presents.

A key component to the success of HIR projects, and the carbon farming industry more broadly, is capturing and sharing land management activities being undertaken as a part of a project. Land managers need to be able to demonstrate to regulatory bodies and the broader market the work that they are doing, and the causal relationship with storing carbon in the landscape. They also need a means to record and store this information over time. This can be a challenge due to the remoteness and scale of rangeland properties, and the ways of working that the people living in these areas may be accustomed to. But it is particularly critical to methods like HIR that rely predominantly on models and remote sensing to determine changes in stored carbon over time, which needs to be supported by this information. Our case study focuses on our use of Fulcrum® to address these challenges.

Fulcrum is an information technology that enables the user to capture and store different types of information with spatial and temporal attributes. We have leveraged the Fulcrum platform to create customised applications tailored to supporting land managers to collect and record the information they need to support HIR projects. Sharing of information is streamlined through automated uploads to a shared platform, facilitating collaboration as things happen. The entries then act as a database for the project, which enables information on historic land management to be easily accessed, providing further opportunities to support management learnings over the long term. In addition, the adoption and use of an information technology like Fulcrum opens opportunities to different ways of working with and supporting land managers. Fulcrum allows the user to visualise themselves and the activities they undertake in the context of other relevant spatial and temporal information such as infrastructure, livestock, vegetation and land types, and carbon estimation areas. On a smart device, this can be done while on the ground and travelling around a property, which provides great potential to support monitoring and decision making in these areas more broadly (Robertson et al. 2019).

This case study explores the adoption of Fulcrum across the portfolio of HIR projects that we service in the southern rangelands of WA. It is intended to demonstrate the potential for the adoption of new ways of working through information technologies to support and empower land managers in Australia's rangelands to take part in carbon farming opportunities and enhance land management more broadly.

Methods

Study region

The southern rangelands of WA include the Gascoyne, Murchison, and the Goldfields-Nullarbor regions – a total area of approximately 503,120 square kilometres (DPIRD 2022). These areas border the south-west agricultural region and are characterised by semi-arid to arid climates with variable and inconsistent rainfall. They are dominated by natives shrublands which support pastoralism through the grazing of livestock, which is the dominant land use of the area. There are 284 pastoral stations across the southern rangelands with an average size of around 185,000 hectares, which are typically run by families or individual land managers. As a result, these areas have limited connectivity and are some of the most remote and sparsely populated regions in Australia. This influences ways of working for people in these locations and makes communication and collaboration challenging.

Study context

We created a Fulcrum account for 32 HIR projects that we service in the southern rangelands of WA. The land managers were given the option of using the created Fulcrum account to record and share activities associated with their HIR projects in the 'Management Activities Application' ('MAA'), which is the custom application we created for this purpose. We supported land managers with the initial installation of Fulcrum on their smart devices and the use of the MAA. The projects commenced between 2018 and 2022, but the majority commenced in 2018 (22 of the 32). Associated Fulcrum accounts were typically activated shortly after this, generally within the first 12-months of commencing the project. Therefore, land managers in this study had access to a Fulcrum account for between three and six years, but most were in their sixth year. A second version of the MAA was developed and commissioned in 2021 to simplify the application in response to feedback. Land manager accounts were then transitioned to the new version of the MAA.

Method overview

We analysed KPIs for the database of the MAA to understand land managers' use of Fulcrum over the study period. The KPIs were assessed across the study period as a whole and on a 12-monthly basis commencing from the initial activation of each individual account. Most of the HIR projects report on an annual basis and so assessing on this timeframe generally captures the breadth of activities associated with a land manager's management system and provides the opportunity to better understand the utilisation of Fulcrum over time.

User adoption

User adoption was calculated based on whether or not a land manager commenced using the MAA to record project information. This was determined for the study period as a whole and across 12-month periods following activation of their Fulcrum account. Adoption was calculated as a binary yes/no for each land manager, with any level of use during the relevant period equating to a 'yes' outcome.

Drop-off rates

Drop-off rates were calculated based on whether land managers continued to use the MAA after initial adoption. This was calculated by determining whether land managers were actively recording activities in each subsequent 12-month period following the initial 12-month period in which they first starting using their account. Drop-off was determined as a binary yes/no for each land manager, with no use by the land manager during a 12-month period equating to a 'yes' outcome. Consecutive years of drop-off with no subsequent activity in the study period were deemed as complete drop-off.

Relative utilisation

Relative use was calculated for each 12-month period to provide greater insight into the effectiveness of Fulcrum in supporting land managers in the way it was designed to. This was calculated as the percentage of the total MAA entries that were created by land managers for each period. Where entries are not created by land managers, we as the service provider create these entries for the land managers by obtaining the information directly from them or during site visits.

Results

User adoption

Land managers for all except one of the 32 Fulcrum accounts that were activated went on to use the MAA at some stage, giving an adoption rate of 97 percent over the study period. Of these, 87 percent commenced using the MAA within the first 12-months following the activation of their account.

Drop-off rates

Of the 31 land managers that adopted the use of Fulcrum at any stage, four have dropped-off completely, giving a drop-off rate of 13 percent over the study period. Of the 27 land manager accounts that have remained active, 41 percent had a partial drop-off period of at least 12-months, and 22 percent for over 12-months. This was most consistently in the year immediately after they commenced using the MAA, with 82 percent of partial drop-offs commencing in the second year. A return to active use of the MAA occurred for 73 percent of land managers that dropped off, and this generally coincided with the transition of land managers to the updated version of the MAA.

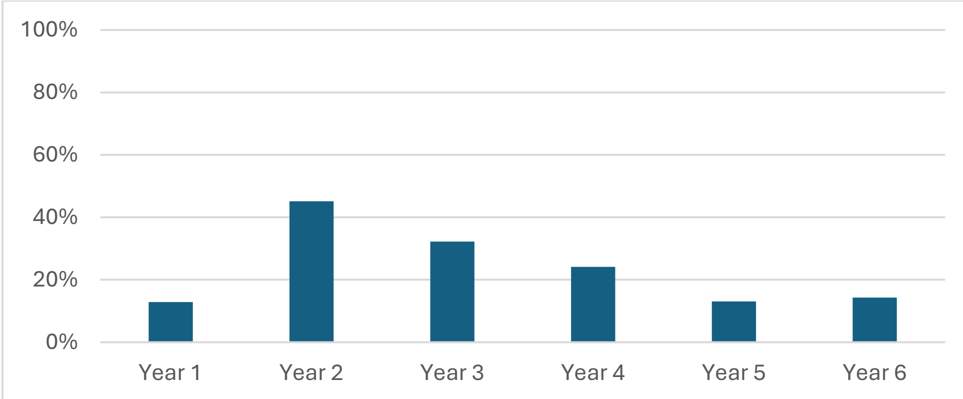

Fig.1: Percentage of land managers that dropped off for each 12-month period following account activation.

Relative utilisation
The average land manager share of MAA entries was 87 percent in the first year. It then reduced to almost half during years 2 and 3. This coincided with the peak in drop-off rates, during which we as the service provider created more entries on behalf of land managers. Between years four and six the average land manager share of entries was between 72 and 80 percent.

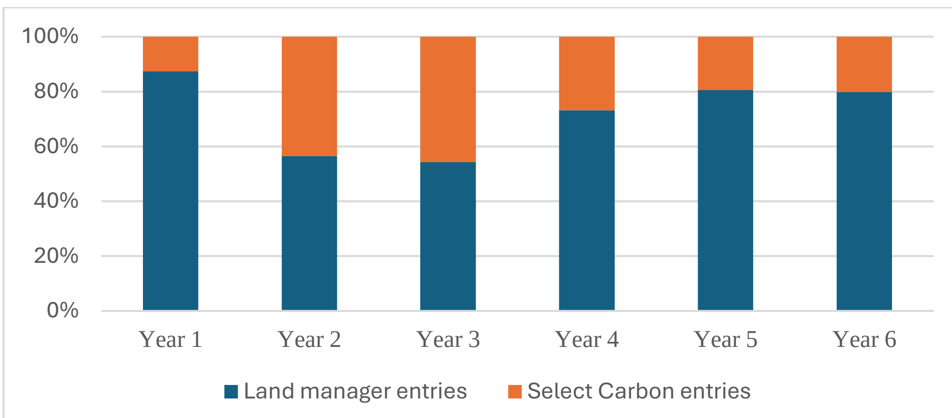

Fig.2: Average percentage MAA entries created by land managers relative to those created by us as the service provider for each 12-month period following account activation.

Discussion
The high adoption rates for Fulcrum show that land managers were receptive to trialling a new information technology to facilitate participation in a HIR project despite most not having used similar technologies in the past and having different existing processes in place to support land management. Our engagement approach was designed to streamline land managers' access to using the MAA by supporting the initial set-up and use of Fulcrum on their smart devices. The majority of land managers then commenced using the MAA within the first year of their account being activated and with high autonomy. That most have since been retained as active users suggests the engagement process was effective in supporting land managers adopt new ways of working to support their participation in a HIR project. The continued use of the MAA also indicates that Fulcrum was a functional solution that has addressed a key challenge faced by land

managers in these locations by supporting them to record and share information required for HIR projects in more effective ways than existing approaches.

The recovery in use of the MAA by land managers aligns with the transition of the majority of land managers to a simplified version of the MAA. Simplification of the MAA was undertaken in response to feedback and to improve workability. The number of options and fields for data entry were reduced and the structure was made more consistent. The subsequent improvement in both active accounts and relative utilisation by land managers demonstrates the effective ongoing engagement and collaboration facilitated by the platform, and the importance of this in effectively establishing and maintaining new ways of working that support ongoing participation in new industries such as carbon farming.

These results demonstrate the successful adoption and ongoing use of Fulcrum by land managers in remote rangeland locations to support their active participation in carbon farming opportunities. This is a significant outcome considering the lack of prior use of similar information technologies for most of these land managers. The benefits associated with the HIR opportunity would have played a role in initial willingness to adopt the use of Fulcrum (Baumber et al. 2022), but the ongoing engagement and collaboration has been key to the sustained success of this collaborative approach. The establishment of these ways of working over the Fulcrum platform presents broader opportunities to support land management in these remote rangeland environments. Farm data platforms widely used in other sectors are largely absent from the pastoral study area. There is further scope for Fulcrum to provide wider property record keeping solutions and to act as a decision support tool through its ability in collecting and visualising data on the ground. It also opens the door for increased collaboration between land managers and a range of governmental and other private services. Further engagement and research using methods such as surveys would be beneficial in understanding how land managers in these areas can best realise these opportunities.

Leveraging Earth Observation services for enhanced livestock farming productivity

Domenech[1], C; Suárez, J[1]; De la Fuente, D [1]

[1]GMV, Isaac Newton, 11 Tres Cantos, 28760, Madrid, Spain, cdomenech@gmv.com;

Key words: Livestock farming, productivity, precision pasture, dry matter biomass, satellites

Abstract

Under the European Space Agency's Global Development Assistance (GDA) programme, GMV leads a pilot project in Paraguay with the World Bank and FECOPROD to enhance livestock farming using Earth Observation (EO) services. By integrating EO-derived data into FECOPROD's digital systems, the project optimizes grazing, monitors water availability, and prevents overgrazing, improving resource management and reducing environmental impact. Dry matter biomass is estimated using the Carnegie-Ames-Stanford Approach (CASA) model, which leverages Sentinel and Landsat data, meteorological inputs, and environmental stress factors. These insights predict pastureland condition and yield, aligning feed production with seasonal cycles for efficient, cost-effective operations.

The EO-based approach provides farmers with detailed land condition data, enabling informed decisions on breeding, health, and farm management. This scalable solution fosters sustainability in livestock farming, reducing environmental pressures while boosting productivity and resilience for Paraguay's agricultural sector and beyond.

Introduction

Two principal methodologies exist for estimating dry matter biomass (DMB): direct modelling using vegetation indices and productivity models (Wenquan et al., 2024). Productivity models, particularly net primary productivity (NPP)-based approaches, are divided into three categories: climate-based models, physiological/ecological models, and light use efficiency (LUE) models (Pei et al., 2024). The widely used CASA model exemplifies LUE models, leveraging remote sensing data for broad applicability (Wang et al., 2022).

This study emphasizes the use of multispectral imagery, with the Moderate-Resolution Imaging Spectroradiometer (MODIS) onboard Terra and Aqua satellites being historically dominant. Since the Sentinel-2 (S2) missions began in 2017, the CASA model has been employed to generate NPP maps at higher spatial resolution (Fang et al., 2021). In addition to EO data, the CASA model requires climate inputs, such as the ERA5-Land dataset, which provides global climate reanalysis data with high spatial and temporal resolution.

The NPP calculation using CASA involves several key steps, notably the estimation of the fraction of Absorbed Photosynthetically Active Radiation (fAPAR). Traditional fAPAR derivation relies on long-term Normalized Difference Vegetation Index (NDVI) data. However, red-edge bands in S2 data improve on NDVI by addressing saturation issues in crop biomass estimations (Fang et al., 2021). While previous studies focus on seasonal or annual NPP calculations, this study targets 10-day intervals. Shorter intervals increase gaps caused by cloud cover, necessitating gap-filling techniques to preserve phenological trends in fAPAR time series. Such approaches also enhance cumulative DMB estimates (Chen et al., 2004).

To mitigate NDVI saturation, this study applies the Beer-Lambert law to fAPAR calculation, linking it to Leaf Area Index (LAI). The Simple Sentinel-2 LAI Index (SeLI), derived from near-infrared and red-edge bands, is used for LAI estimation (Pasqualotto et al., 2019). Reflectance composites over 10-day periods, integrating bands from blue to shortwave infrared (SWIR), are generated by selecting the day with maximum NDVI, ensuring consistent data quality.

Like fAPAR, albedo is integral to CASA's NPP computation, particularly in Photosynthetically Active Radiation (PAR) estimation (Wang et al., 2022). Using S2 reflectance composites and methods from Landsat-8/9 OLI data processing, S2 albedo is calculated (He et al., 2018). As OLI and Sentinel-2 MSI sensors provide comparable imagery, harmonization between the missions is feasible.

The LUE parameter, crucial in NPP estimation, reflects the relationship between biomass accumulation and solar radiation use efficiency. It is influenced by multiple factors and can be derived empirically from photosynthetic responses or simulated using ground-based or global datasets (Propastin et al., 2012).

Converting cumulative NPP into DMB requires field data specific to vegetation types, such as carbon allocation capacity ($C_{allocation}$) and root-to-shoot biomass ratios (Fu et al., 2023). In the absence of local data, global or regional studies may be used (Bolinder et al., 2006).

This study aims to produce 10-day DMB estimates, resulting in 36 maps annually. Such time-series data provide sufficient temporal resolution for phenometric analysis, offering an alternative to spectral indices commonly used in phenology studies. The detailed 10-day DMB profiles facilitate identification of critical phenological events and their corresponding biomass values.

Methods

The study area covers 1,260 km² in Paraguay's Central Chaco region, spanning longitudes 59° 58' 12" to 59° 37' 4.8" west and latitudes 22° 35' 38" to 22° 16' 44" south. It includes parts of the municipalities of Loma Plata, Filadelfia, Tte 1º Manuel Fernández, and Mariscal José Félix Estigarribia (Figure 1). This predominantly pasture area hosts trial plots managed by FECOPROD and two dairy farms.

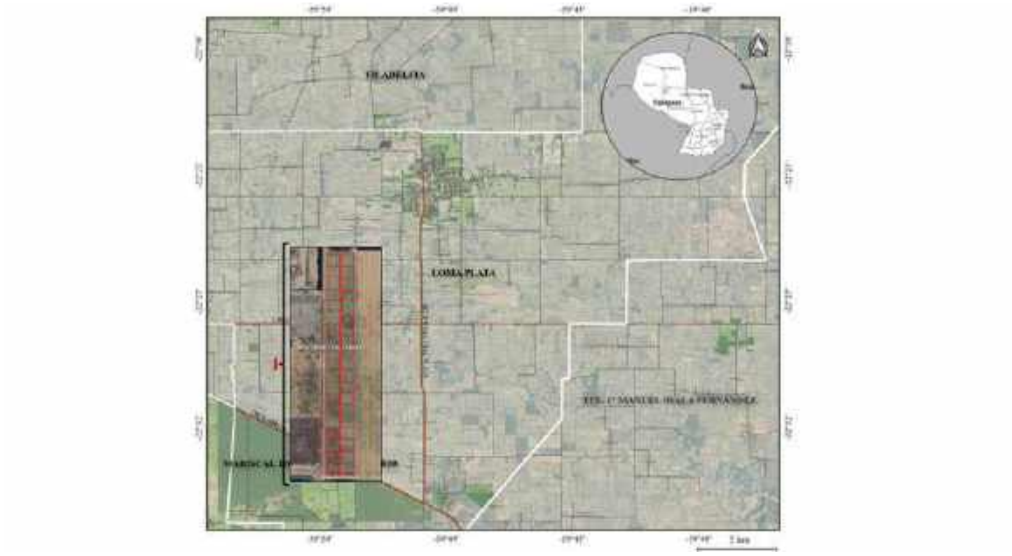

Figure 1 Study area.

The methodology includes four main stages: data collection, time-series preparation, NPP calculation, and DMB calculation with phenometric analysis (PA). The workflow is illustrated in Figure 2 and detailed below.

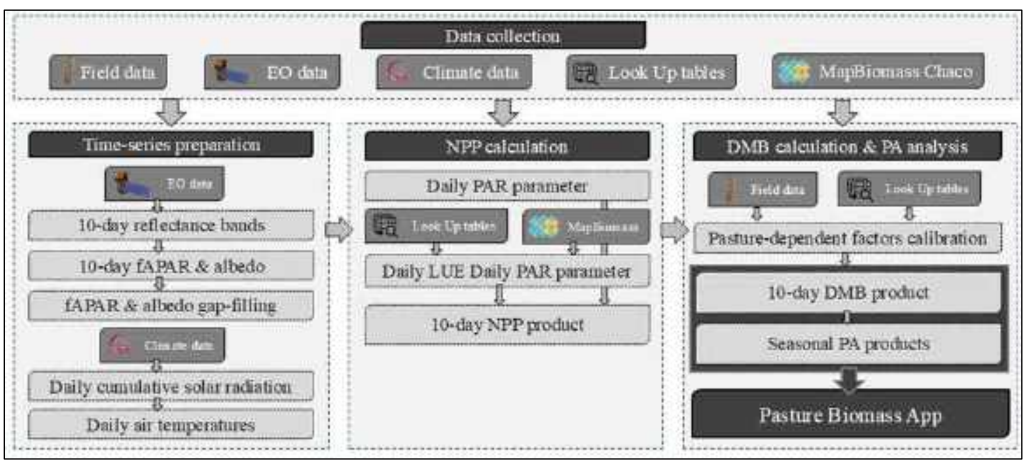

Figure 2 Workflow employed in this study.

Data collection

Data collection involved field data, EO data, climate data, and look-up tables. Field data from FECOPROD included 38 trial plots with forage species' sowing and mowing dates for the 2022 season and average bale weights per species. S2 Level 2A data (2016 onward) provided the EO dataset, while climate data came from the ERA5-Land dataset via Copernicus Climate Data Store (CDS). Look-up tables included global sources like the Biome-Property-Look-Up-Table for MODIS GPP/NPP (Zhao et al., 2005) and $C_{allocation}$ parameters from Bolinder et al. (2006). Pasture maps were sourced from MapBiomas Chaco.

Time series preparation

Daily S2 scenes were used to calculate the NDVImax-day product, which identifies the optimal day within each 10-day period based on maximum NDVI. Using the NDVImax-day, 10-day composites were created for blue to SWIR narrow-bands by assigning reflectance values directly from the sensor rather than averaging. These composites formed the basis for calculating 10-day fAPAR and albedo using equations (1) and (2):

$$fAPAR = 1 - \exp(-k\,(5.405 \cdot (SeLI - 0.114)) \quad (1)$$

$$albedo = 0.0134 + 0.246\,blue + 0.146\,green + 0.191\,red + 0.304\,nir + 0.105\,swir1 + 0.008\,swir2 \quad (2)$$

Here, SeLI (Pasqualotto et al., 2019) was used to estimate fAPAR, and the albedo equation for OLI sensors (He et al., 2018) was adapted for S2. Time-series gaps in fAPAR and albedo were addressed through outlier removal, a combination of interpolation and forward-fill methods, and Savitsky-Golay smoothing (Chen et al., 2004). Climate data, including solar radiation (SSRD) and minimum air temperature (TMIN), were generated daily from CDS.

NPP calculation

The CASA model calculated NPP using equations (3) to (6):

$$PAR\,[MJ/m^2/day] = SSRD\ (1 - albedo) \quad (3)$$

$$tmin_{LUE}\,[^{o}C] = (TMIN - tmin_{min})\,((1 / (tmin_{max} - tmin_{min}))) \quad (4)$$

$$LUE\,[gC/MJ/day] = LUE_{max}\ tmin_{LUE} \quad (5)$$

$$NPP\,[gC/m^2] = fAPAR\ LUE\ PAR \quad (6)$$

Parameters $tmin_{min}$, $tmin_{max}$, and LUE_{max} were derived from the Biome-Property-Look-Up-Table (Zhao et al., 2005).

DMB calculation

DMB was calculated using equation (7):

$$DMB = \sum NPP\ (root\text{-}shoot\ ratio / C_{allocation}) \quad (7)$$

Field trials were conducted to calibrate the root-to-shoot ratio parameter. NPP time-series data were accumulated throughout the 2022 season, and by grouping field trials with the same forage species, average total NPP values were compared to ground-truth bale weights. At this stage, the $C_{allocation}$ value was adopted from Bolinder et al. (2006), and the root-to-shoot ratio was calibrated for each forage species.

Since no forage species map was available outside the field trials, the root-to-shoot ratio used to infer DMB in the Chaco region was approximated as the average value of all calibrated forage species. This average ratio (0.4136) aligns with previous findings for the Chaco region (Baldassini et al., 2020).

The following table compares ground-truth bale weights (kg/ha) with DMB estimates from the CASA model (LUE approach) for each forage species in the 2022 field trials, applying the average root-to-shoot ratio instead of the species-specific calibrated values. During model calibration, the accuracy achieved was a coefficient of determination (R^2) of 0.87 and a root mean square error of 29.03%.

Table 1 Ground-truth bale weights (kg/ha) vs. CASA model DMB estimates using the average root-to-shoot ratio in 2022 field trials

Forage species	DMB - Bale weights [kg/ha]	DMB - LUE approach [kg/ha]
Callide	4,735	4,712
Cayman	2,438	2,605
Dicantio	2,705	2,968
Gatton panic	2,475	2,484
Lucero	3,370	3,127
Paiaguas	3,800	3,306
Quenia	2,525	3,017
Ruziziensis	3,860	3,555
Tamani	2,103	2,254

Using the calibrated root-to-shoot ratio, 10-day DMB products were generated for the entire study area, enabling phenometric analysis with high temporal resolution. This approach allows tracking of phenological events and biomass trends in pastures at 10-day intervals. While ground-truth data from FECOPROD field trials ensured proper model calibration, additional in-situ DMB data from other locations within the inference region were unavailable. As a result, DMB estimates could not be validated outside the Chaco region, except for the comparison shown in the previous table.

Results

The catalogue of products from this study is available through the Pasture Biomass Production App (last accessed November 2024). The products, at a 10-meter resolution, include:

- 10-day DMB
- Total DMB annually
- PA products such as start, peak, and end of season (times and DMB values)
- Daily DMB increase or decrease rates from start to peak times or from peak to end times

These products can be compared using the 'Split Map' mode. Additionally, by activating the contextual layer for Pastures experimental plots and selecting 'Display timeseries for selected product,' time-series statistics at the trial plot level are shown when clicking on each plot. Figure 3 illustrates the 10-day DMB product. The DMB products start on fixed days (1, 11, and 21), so the length of the last 10-day interval varies depending on the month.

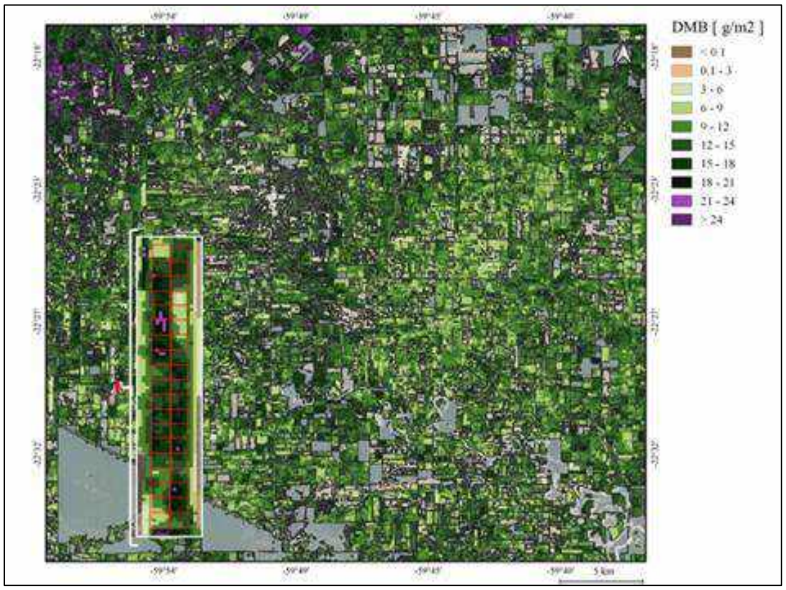

Figure 3 10-day DMB product. DMB generated in the interval 11th-20th, January 2022.

Discussion and conclusions

This study primarily uses datasets from the Copernicus services, but the processors are adaptable to other sources. The time series preparation strategy enables 10-day interval pasture monitoring. Unlike most studies that use a fixed albedo value, this study employs a detailed, updated albedo product from EO data.

The pasture map can be replaced with other maps, such as farm cartography or species-specific maps, as the root-shoot ratio parameter was calibrated for various forage species. The $C_{allocation}$ parameter and environmental stress factors in the LUE calculation were fixed based on local information, but alternative approaches can be considered.

FECOPROD, while technically advanced in data acquisition, lacked the ability to add value to the recorded information. It needed to analyse available data with EO data to generate value-added information like dry matter biomass and its variability over different time spans. The study's initial objectives were achieved, providing a scalable solution that addresses environmental concerns, promotes resource management, and enhances the sustainability of the livestock industry in Paraguay and beyond. This contributes to a more efficient, productive, and environmentally conscious agricultural sector.

Acknowledgements

We extend our gratitude to FECOPROD and Copernicus services for providing the datasets used in this project. We also thank the World Bank for initiating and supporting this effort as a key partner in Paraguay's livestock sector improvement. Special thanks go to the ESA Global Development Assistance (GDA) Programme for funding the project.

Key words: 3D models; adaptative grazing; spatial heterogeneity; multi use rangelands.

Abstract

The use of drones in studies of rangeland ecology and management has increased significantly in the last 10-15 years. Drone imagery has been used to measure woody cover, forage biomass, spatiotemporal changes in vegetation cover, rangeland condition, and to monitor wildlife habitat in rangeland systems. The development of 3D models derived from drone imagery has facilitated new opportunities to quantify the spatial structure of land cover. For example, fine-scale structural changes influenced by grazing can be quantified using drones and subsequently translated to potential impacts on wildlife habitat. Technological developments like terrestrial LiDAR systems and higher resolution imagery allows for the improvement on the understanding of very-fine scale ecological processes in these dynamic systems. These terrestrial sensors can add valuable information to the current airborne data collection systems.

However, there is still a need to evaluate the relationship between different drone-based sensors and how the information collected and analysed can be integrated into traditional rangeland metrics. More importantly, we seek to better understand how to translate these analyses and metrics into practical management information that is critical for these socio-ecological systems. Here we demonstrate (1) the use of multispectral imagery to quantify the configuration of brush cover in semiarid landscapes, (2) the use of 3D drone data to assess the fine-scale impact of grazing on upland game birds (*Galliformes*), and (3) the integration of LiDAR, multispectral, and natural color cameras to generate data to inform livestock and wildlife habitat management. Finally, we provide insights on how drone technology could be potentially used in the future to assist in rangeland management to forecast forage growth and multi-species use for wildlife objectives.

Introduction

The use of remote sensing in rangelands has been critical to understand landscape level processes (Allred et al. 2021, Rhodes et al. 2022.) In the last 50 years, a variety of satellite platforms have been used to estimate forage production (Rhodes et al. 2022, Bestelmeyer et al. 2024) and vegetation spatial configuration to integrate this information with livestock production and wildlife habitat management. In the last 15 years, the development of drone technology has emerged as a new opportunity to collect data at very-high spatial and temporal resolutions and provides a bridge between satellite imagery and field-based data collection (Rango et al. 2006, Jackson et al. 2020, Perez-Luque et al. 2022, Avila-Sanchez et al. 2024). Derived products in 2D and 3D formats from drone data acquisitions have been used to quantify woody vegetation height (Page et al. 2022), estimate forage biomass (DiMaggio et al 2020, Perotto-Baldivieso et al. 2021), determine spatiotemporal changes in vegetation cover (Perez-Luque 2022), determine rangeland condition (Amputu et al. 2023) and monitor wildlife habitat in rangelands (Friesenhahn et al. 2023, Zabel et al. 2023). Drones offer flexibility in the variety of sensors that can be utilized to collect data. Some of the most popular sensors include natural color (with pixel resolutions from 20 to 129 megapixels), multispectral, hyperspectral, thermal-infrared and LiDAR. However, there is still a need to evaluate the relationship between the different drone-based sensors and how this information collected and analysed can be integrated into rangeland metrics. More importantly, we seek to better understand how to translate these analyses and metrics into practical management information using consumer grade drones. We demonstrate (1) the use of multispectral imagery to quantify the configuration of brush cover in semiarid landscapes, (2) the use of 3D drone sensors acquired data to assess the fine-scale impact of grazing on upland game birds (*Galliformes*), and (3) the integration of LiDAR, multispectral, and RGB cameras to generate information for livestock and wildlife habitat management. Finally, we will provide future directions on how drone technology could be potentially used to assist in rangeland management to forecast forage growth and multi-species use for wildlife objectives.

Multispectral imagery for estimating woody cover configuration

The increasing spatial and spectral resolution of multispectral cameras to acquire rangeland imagery generates new opportunities to assess woody vegetation cover, composition, and spatial configuration, particularly in semiarid and arid landscapes. For instance, the Tamaulipan thornscrub (hereafter "thornscrub") ecosystem is characterized by dense, diverse shrub, arid-adapted shrub communities and provides critical habitat for endemic and endangered species (Jahrsdoerfer and Leslie 1988, Creacy 2012, Mohsin et al. 2021). This ecosystem, located within northeastern Mexico and South Texas, USA, has been reduced to <2% of its historic distribution due to novel pressures related to urbanization, woody plant removal for livestock forage production, and land use change (Jurado et al. 1998, Ricketts et al. 1999, Lombardi et al. 2020). Little information exists on its current distribution, but it is estimated that there is >75% native mixed brush cover in these communities (Flores 2019). Our objective was to evaluate the feasibility of identifying brush species composition within this complex community using very-high resolution multispectral imagery. We used a MicaSense Altum Multispectral camera that collects imagery in six spectral bands: blue, (443 – 507 nm), green (533 – 587 nm), red (654 – 682 nm), red edge (705 – 729 nm), near-infrared (785 – 899 nm), and long wavelength infrared (8000-14000 nm; MicaSense 2019). Images were collected in five plots (0.4 ha per plot) in Webb County, Texas, USA. Each flight was conducted at an altitude of 21 m aboveground level with an 80% image overlap in September 2022. Once images were acquired, they were processed in Pix4D mapper (Pix4D Inc., San Francisco, CA, USA) to create orthoimagery, a digital terrain model and a digital surface model. We then used the orthoimagery to classify vegetation cover. We subtracted the digital terrain model from the digital surface model to estimate a canopy height model to remove the herbaceous layer and focused on the shrub components. We conducted an accuracy assessment (i.e. confusion matrix) with 643 points collected within the plots. Our image classifications yielded overall accuracies of 78%. We were able to correctly classify 19 out of the 24 species present in our study area: guajillo (*Acacia berlandieri*), blackbrush (*Acacia rigidula*), shrubby blue sage (*Salvia ballotiflora*), cenizo (*Leucophyllum frutescens*), chomonque (*Nahuatlea hypoleuca*), coyotillo (*Karwinskia humboltiana*), desert yaupon (*Schaefferia cuneifolia*), lime prickly ash (*Zanthoxylum fagara*), honey mesquite (*Neltuma glandulosa*), huisache (*Acacia farnesiana*), Texas persimmon (*Diospyros texana*), prickly pear (*Opuntia engelmannii*), Spanish dagger (*Yucca treculeana*), Texas kidneywood (*Eysenhardtia texana*), whitebrush (*Aloysia gratissima*), oreja de raton (*Bernardia myricifolia*), la coma (*Sideroxylon celastrinum*), allthorn (*Koeberlinia spinosa*), and granjeno (*Celtis pallida*). These techniques have proved promising towards obtaining scalable estimates of woody plant composition and configuration within this imperilled ecosystem characterized by high woody plant species richness and complexity.

Fine-scale assessment of herbaceous cover during cattle (*Bos taurus*) grazing

The development of 3D models derived from drone imagery has opened new opportunities to integrate 3D model classifications to evaluate the spatial heterogeneity of vegetation cover in rangelands (Avila-Sanchez et al. 2024). To illustrate this concept, we conducted a study in a pasture grazed by cattle with adaptive management (Derner et al. 2022, Avila-Sanchez et al. 2024) in Duval County, Texas, USA. The principle behind adaptive management is to use grazing as a tool to change herbaceous vertical structure (stubble height) to create or enhance wildlife habitat, in this case, for northern bobwhite (*Colinus virginianus*). Once average herbaceous stubble height of 30 cm was obtained, cattle were moved to a different pasture. We flew seven sites (27 ha each) at an altitude of 50 m above ground level (DiMaggio et al. 2020) with a 70° camera angle, 80% overlap, and a 20 megapixel natural color camera. We acquired natural color imagery that was processed in Pix4D (Pix4D Inc., San Francisco, CA, USA) to generate an orthoimage, a digital surface model, and a digital terrain model. We subtracted the digital surface model from the digital terrain model to obtain a canopy height model. We classified the canopy height model pixel values into five different height classes (Avila-Sanchez et al. 2024): bare ground (0 to < 5 cm), low herbaceous vegetation (5 to < 30 cm), grazing target height herbaceous vegetation (30 to < 40 cm), tall herbaceous vegetation (40 to < 120 cm), and brush/shrubs (> 120 cm; Fig. 1). The classified raster image was used to assess the amount and spatial configuration of the different vegetation classes using landscape metrics at the class level: percent class cover, patch density (PD; patches/ha), and mean patch area (MPA; m²) (Fragstats 4.2; McGarigal et al. 2023). We found that this grazing system provided 51.9% ± 5.80% low herbaceous vegetation cover and 9.55 ± 6.15% grazing target height herbaceous vegetation cover within managed pastures. The configuration of this cover resulted in a large number of small patches in the low herbaceous vegetation (PD=49,222 patches/ha [SE= 6,821 patches/ha]) and MPA= 12.14 m² [SE=2.08 m²] and the grazing target height herbaceous vegetation (PD=111,036 patches/ha [SE= 28,525 patches/ha]) and MPA= 1.14 m² [SE=0.14 m²]) covers. Moreover, the spatial configuration of stubble height in these grazed pastures were within the required vegetation cover configuration requirements suggested for northern bobwhite habitat (Hernández and Guthery 2012).

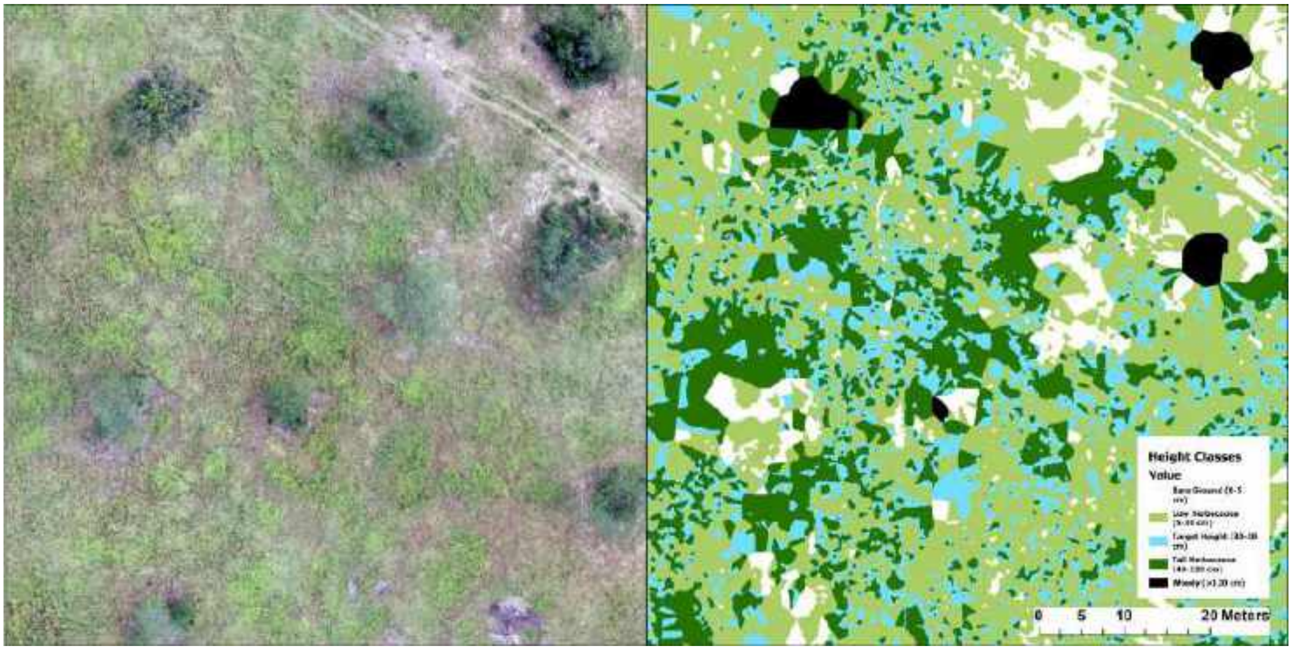

Figure 1: Example of classified vegetation height maps from drone-based imagery. white represents bare ground (<5cm), light green represents low herbaceous (5-30cm), cyan represents target grazing height (30-40cm), dark green represents tall herbaceous vegetation (10-120cm), and black represents woody vegetation (>120cm).

Integrating LiDAR, multispectral, and natural color data in rangelands to derive rangeland metrics
While consumer-drone data can provide substantial information towards managing rangelands, there is still a need to evaluate the relationship between the different drone-based sensors and how the information collected and analysed can be integrated into rangeland metrics. More importantly, we seek to understand how we can translate these analyses and metrics for outreach and management purposes. Therefore, our goal is to develop methodologies and approaches that can identify proxies that can be used by ranchers and managers to assess rangeland health and condition at the pasture scale for livestock and wildlife operations. We plan to achieve this objective by collecting data in a 1200 ha research facility in South Texas, USA. Data collection is being conducted during the growing season (March-April) and at the beginning of the dormant season (September-October). We have selected a variety of land cover types (e.g. open grass, interspersed savannah, and closed canopy brush) to collect vegetation cover information. Within these land cover types, we are marking 80-100 locations using Planet imagery (daily 3-m resolution satellite imagery) based on current land management practices. We are acquiring drone-based data within two weeks of field data collection: natural color, multispectral, hyperspectral, LiDAR, and thermal data. We will select 5-10 locations and collect vegetation data using line transects similar to DiMaggio et al. (2020). Once the information is collected in the field, we will complement it with a terrestrial mobile station to collect 3D vegetation structure. Data collected with different sensors and field data will be analyzed to evaluate the relationship between data collected in the field and sensor data following similar approaches used by DiMaggio et al. (2020), Page et al. (2023), and Massey (2023). With these data, we will build a model that links multiple sensor information to natural color data to significantly improve our ability to derive information from less expensive drones with more efficient approaches. This will increase the opportunity to adopt natural color technology by ranchers to assess a variety of metrics in rangelands.

Conclusions

The case studies highlighted in this manuscript provide a good example of the opportunities that drone technology can provide for management of multiple species in rangelands. We used technology to evaluate the use of multispectral data to assess woody cover composition in rangelands and the assessment of herbaceous vegetation cover spatial heterogeneity managed by grazing to provide a potential proxy for vegetation composition complexity. Finally, we are integrating information from multiple drone sensors to develop proxies into a meaningful and user-friendly landowner tool and resource that will be key to maintaining producer efficiency and stewardship without compromising rangeland integrity.

Fusion of pixel & object-based image analysis to improve stratification of soil carbon projects in the semi-arid rangelands, Australia

Newey, L[1]; Hackney, B[1]; Rigg, JL[1]; Wicks, T[1]; Orgill, SE[1]

[1]Select Carbon, 275 George Street, Brisbane, QLD 4000, Australia.

Key words: soil carbon; soil sampling design, stratification, image analysis

Abstract

Soils in the semi-arid rangelands of southeastern Australia are inherently low in organic carbon (SOC) content due to a combination of climatic and historic land degradation factors. Small increases in SOC attributable to improved management in such expansive landscapes offers an opportunity to restore rangeland function and play an important role in mitigating climate change.

Soil Organic Carbon stocks and fluxes are influenced by complex interactions between plant growth, climate, soil type, topography and land management resulting in high spatial and temporal variability. Variability creates a challenge for designing soil sampling strategies to detect small, incremental changes in SOC. In the rangelands, this challenge is accentuated by low SOC stocks, low SOC sequestration rates, presence of soil inorganic carbon and cost of labour-intensive soil sampling programs across large pastoral properties. Optimal stratification by clustering homogenous areas within a paddock, combined with adequate sampling density can reduce variance and improve SOC stock estimations.

Remotely sensed earth observation data can be used to determine stratification in soil carbon projects. This paper presents a basic stratification framework that integrates multiple sources of high-resolution landscape data. The study area is a dryland crop and grazing property located in the semi-arid rangelands of New South Wales (NSW). The method fuses a temporal ground cover raster classified by pixel-based analysis, with a segmented image processed by object-based image analysis. The success of the stratification can be judged by a moderately small variance in mean SOC within each carbon estimation area (CEA) and for the total project area. A validation baseline survey is planned for February 2025.

Introduction

Rangelands play an essential role in sequestering carbon to offset greenhouse gas emissions in Australia. Semi-arid soils contain naturally low levels of soil organic carbon (SOC) (Orgill et al. 2017). Small increases in SOC which may occur over time with improved management of rangeland systems offer the opportunity to sequester a significant amount of carbon over an extensive area (Orgill et al. 2017). However, detecting the differences due to management are problematic to measure and rely on high quality soil sampling stratification (Beverly et al. 2024). Soil sampling stratification can improve SOC estimation efficiency and accuracy to detect and monitor temporal changes (Potash et al, 2023). Current attention is focused on understanding and measuring influences of management practices and climate fluctuations on SOC (Bastin et al.2024, Orgill et al. 2017). Effective stratification is vital to capture small changes in SOC over large project areas, allowing the opportunity for carbon sequestration in rangelands to be quantified. A strategic low-cost baseline stratification of rangeland soils will be a critical first step towards accurate SOC reporting and monitoring change over time.

This paper focuses on the application of remotely sensed high-resolution temporal ground cover and soil colour imagery to enhance stratification design in soil carbon projects. Soil colour is a potentially useful attribute to stratify for SOC because the soil organic matter of which the carbon is part is a primary determinant of soil colour (ref: Leeper & Uren, 1993?). The approach fuses a temporal ground cover raster classified by pixel-based analysis (unsupervised classification), with a segmented image processed by object-based image analysis (OBIA) using dry soil colour reflectance.

Pixel-based analysis is processed on a per pixel level, using only the spectral information available for that individual pixel, values of neighboring pixels are ignored. A common example of pixel-based analysis is unsupervised classification which groups pixels based on statistical similar class means without training data. This unbiased technique can reveal hidden patterns in the landscape not clearly visible in the imagery. By comparison, OBIA groups pixels together based on how similar they are in colour and shape to adjacent pixels using both spectral and spatial information for classification. Image segmentation tends to generate objects that resemble real-world landscape features. The aim of this paper is to combine the benefits of pixel-based classified ground cover with object-based segmented soil colour in comparing landscape features to enhance the stratification process.

Methods

Temporal Ground Cover

The study area is a dryland crop and grazing property located in the semi-arid rangelands, NSW. Seasonal fractional cover Sentinel-2 (10 m resolution) created by the Joint Remote Sensing Research Program & Department of Environment and Science, was sourced to provide insight into ground cover spatial variability over time. The product is based on the JRSRP Fractional cover V3.0 algorithm applied to Sentinel-2 Level 1C data from the ESA (Joint Remote Sensing Research Program, 2023). A multilayer perceptron model was used to estimate percentage of cover in three fractions, bare ground, photosynthetic vegetation, and non-photosynthetic vegetation from surface reflectance (Joint Remote Sensing Research Program, 2023).

The bare fraction from the Seasonal fractional cover product (capture date: December 2018 to February 2019) was classified for each carbon estimation area (CEA) using the ISODATA unsupervised classification task in ENVI. Results were cleaned for isolated pixels. Zonal statistics were generated for each class within each CEA. Classes were then merged if means had less than 5% separation. Polygons <2ha in size were aggregated into larger adjacent polygons of a similar soil colour and ground cover type.

Dry soil colour segmentation

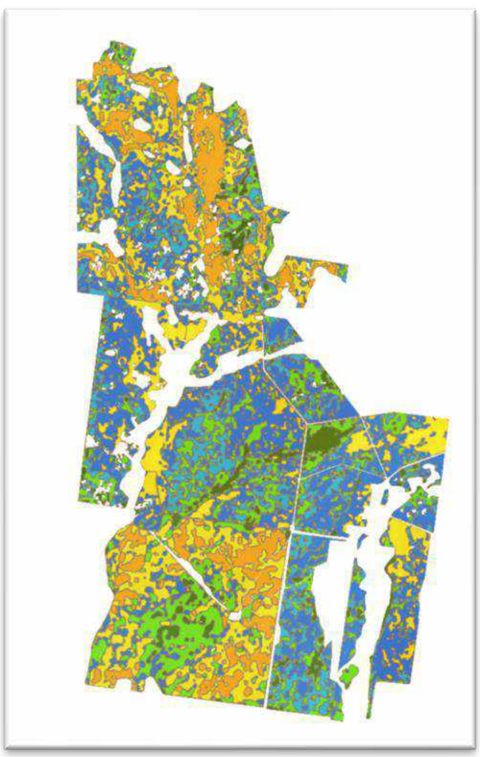
A Sentinel-2 (10 m resolution) true colour image (RGB) captured during a low rainfall period (capture date: 22nd December 2018) was segmented in ArcGIS Pro, using visible bands only (bands 2, 3 and 4). Spectral detail function (The level of importance given to the spectral differences of features in the imagery) was set high on 20 units, spatial detail (The level of importance given to the proximity between features in the imagery) was set at 6 units (minimum segment size in pixels 50). Providing a high-level representative segmentation of soil colour across the study area (Figure 1). The segmented raster output is converted to a vector format, then cleaned and simplified by merging small polygons, then clipped to the study area. Classes were labelled based on soil colour and CEA.

Fusion

The goal is to combine two significant variables that can assistance with visualising SOC spatial variability. Soil colour is the base of the stratification for each CEA. Ground cover polygons will be nested within the soil colour polygons. A union between the two layers was completed for each CEA in ArcGIS Pro. The vector outputs are cleaned by aggregating small, fragmented polygons (<0.5 ha) and slivers. The area of strata within each CEA is reviewed. Small strata will be merged into adjacent larger strata of similar soil colour and ground cover (based on strata means of bare% ground cover).

Results

Stratification based on temporal ground cover resulted 4-5 classes per CEA (Figure 1). Dry soil colour segmentation generated a 4-5 classes per CEA (Figure 2). Combining the two stratification data sets generated 8-10 strata per CEA (Figure 3).



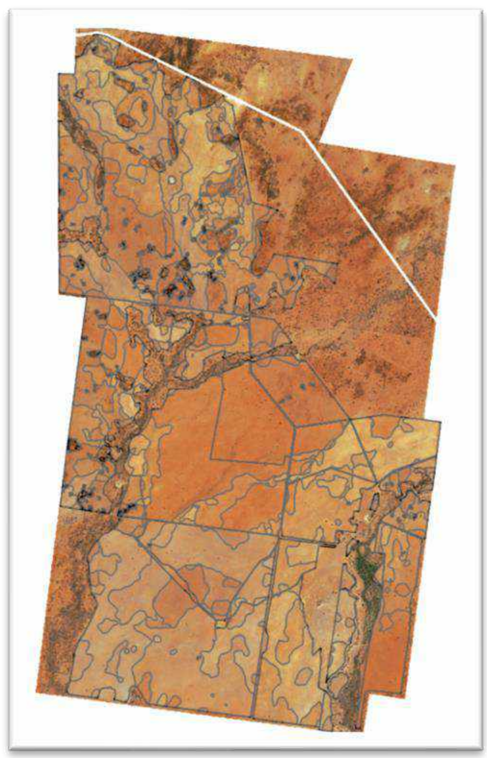


Figure 1. Temporal ground cover classification. Figure 2: Dry soil colour segmentation results.

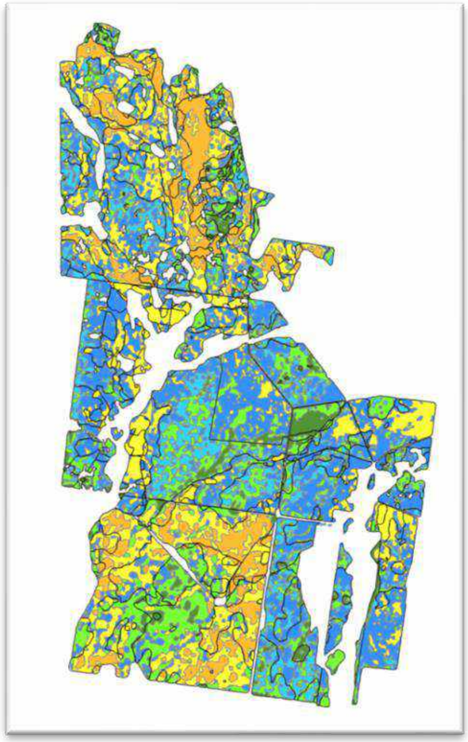

Figure 3. Stratification of ground cover and soil colour.

Discussion

The quantity of SOC in soils is influenced by a combination of factors, predominantly climate, soil type and recent vegetation cover management, plus other factors including topographic position (Grey 2021). The amount of ground cover can also be influenced by soil characteristics (informed by soil colour), management, and differences in topographic position/aspect. Merging ground cover with soil colour increased the number of strata in each CEA.

The patterns of temporal ground cover classification align with the soil colour segmentation outlines (Figures 1 2, & 3). There are similar patterns of stratification when comparing the two layers side-by-side and when both are overlayed (Figure 3). For example, note the center of the bottom southwest paddock, there is a dark red island surrounded by lighter red soil, delineated in both datasets (Figure 3). Similar patterns can be expected due to the interrelationships of soil properties and groundcover. However, there are also differences between the two datasets, that could be related to management practices impacting ground cover within the composite fractional cover timeframe (capture date: December 2018 to February 2019). A validation baseline survey, planned for February 2025, will collect SOC data from each CEA. The success of the stratification will be quantified by comparing the variance in mean SOC within each CEA and for the total project area with that of each individual stratification approach.

While this desktop approach offers a relatively quick and data-driven approach to stratification, it is important to couple it with consideration of on-ground management factors that may influence the results. For example, in drier areas of cropping zones it can be common to incorporate a fallow into a cropping rotation to preserve moisture for a following crop, therefore this may reduce ground cover in those areas. Similarly, the presence of high numbers of feral herbivores (e.g. goats) may result in patch overgrazing of specific areas of the landscape resulting in periodic reduction in ground cover that may not necessarily be indicative of soil production or carbon storage potential.

Key words: Precision livestock technology, dry matter intake, beef cattle

Abstract

Precision livestock technology (PLT) can improve sustainability of beef production on rangelands. Key to the advancement of PLT is the integration of technologies and data streams with animal nutrition models to better inform management decisions. Knowing dry matter intake (DMI) is essential for setting stocking rates and estimating forage removal by grazing beef cattle; however, estimating DMI for grazing cattle is difficult due to dynamic changes in forage quality and animal weight throughout a grazing season. A study was conducted from 2021-2023 at the South Dakota State University Cottonwood Field Station (Cottonwood, SD, USA) to estimate daily DMI for grazing steers. The objectives of our study were to 1) utilize machine learning (ML) to predict daily estimates of forage quality, 2) estimate average daily gain (ADG) using in pasture weighing systems, and 3) incorporate forage quality and ADG estimates into animal nutrition models to predict individual animal DMI. From 2021-2023, bi-weekly forage samples were collected and used to train a multivariate random forest model to predict daily acid detergent fiber (ADF) based on climate and imagery metrics derived from Google Earth Engine. Root mean square error of prediction was 2.6 with a 0.81 correlation between predicted and observed values of ADF. SmartScales™ (C-Lock Inc., Rapid City, SD, USA) were deployed in six pastures to estimate daily animal weights for grazing steers. Smoothing splines were used to estimate ADG allowing for non-linear changes in animal performance. Daily estimates of ADF and ADG were used to calculate daily DMI for individual animals using equations from the Nutrient Requirements of Beef Cattle. Overall, average DMI estimates for individuals ranged from 2-3% of body weight, which is within expectations for free ranging livestock. This paper address how big data, technology, and machine learning can be integrated to better aid grazing monitoring and forage demands for livestock.

Introduction

The promise of precision livestock technology (PLT) is to increase operation efficiency and reduce the associated environmental footprint of grazing on rangeland systems. A suite of recent novel technologies such as remote sensing products to estimate plant fractional cover and net primary production (Jones et al. 2017) and in-pasture weighing systems (Parsons et al. 2023) has enhanced our ability to measure and manage livestock production within rangeland systems. Individually, these technologies can increase the temporal and spatial resolution of data collection that can help inform management decisions at finer scales; however, integration of multiple different technology platforms with machine learning and animal nutrition models is needed to maximize the impact of PLT.

Estimating dry matter intake (DMI) is essential for beef producers to identify more efficient animals and optimize cattle performance. In addition, DMI is an essential component for calculating stocking rates and estimating forage utilization from grazing animals. Estimation of DMI for cattle grazing on extensive rangelands is difficult due to changes in environmental factors, forage quality, and animals' physiological state, which can result in large variability among animals grazing in the same pasture (Galyean and Gunter 2016). Traditionally, fixed estimates of DMI such as 3% of body weight (BW) have been used to calculate forage demands for grazing animals; however, this doesn't account for the dynamic changes in forage quality, animal BW, and DMI inherent within rangeland systems. Previous work has demonstrated the use of models to predict DMI required to achieve a specified level of performance based on animal nutrition equations to determine net energy required for a given animal BW and average daily gain (ADG) (Anele et al. 2014). The integration of in-pasture weighing systems to measure individual animal performance and BW, remote sensing to estimate daily forage quality, and animal nutrition equations may be able to estimate DMI for grazing beef cattle. The objectives of our study were to 1) utilize machine learning (ML) to predict daily estimates of forage quality, 2) estimate average daily gain (ADG) and daily BW using in pasture weighing systems, and 3) incorporate forage quality and ADG estimates into animal nutrition models to predict individual animal DMI.

Methods

Study Site

Research for this study was conducted at the South Dakota State University Cottonwood Field Station (CFS), Cottonwood, SD, USA (43.960297, -101.857913) from 2021-2023. Rangeland at the CFS is typical of a Northern Great Plains mixed-grass prairie, consisting primarily of western wheatgrass (*Pascopyrum smithii* Rydb.), green needlegrass (*Nassella viridula* Trin.), buffalograss (*Bouteloua dactyloides* Nutt.), and blue grama (*Bouteloua gracilis* Willd. Ex Kunth.). This study was overlaid on a long-term experimental grazing study setup as a randomized complete block with three levels of stocking rate replicated in two pastures each (heavy (1.78 AUM/ha), moderate (0.99 AUM/ha), and light (0.79 AUM/ha)) for a total of six pastures. In each of three years, yearling steers (n = 116, 131, 127 in 2021, 2022, 2023, respectively) were stratified by BW into one of six pastures. Steers in 2021 grazed from June 10 to August 17, steers in 2022 grazed from June 8 to August 21, and steers in 2023 grazed from June 6 to August 30.

Remote Sensing

Forage quality was estimated by clipping five bi-weekly georeferenced forage samples from May to October in 2021-2022 across each of the six experimental pastures. Forage samples were dried for 72 hrs in an oven at 60˚C and weighed for biomass. After weighing, samples were ground in a Wiley mill (Thomas Scientific, Swedesboro, NJ, USA) with a 1 mm sieve. Forage digestibility was analysed for neutral detergent fiber (NDF), acid detergent fiber (ADF), and acid detergent lignin (ADL) using a fiber analyzer (ANKOM 200 Fiber Analyzer, ANKOM Inc., Macedon, NY, USA). To develop a predictive model, dependent variables were extracted from Google Earth Engine (GEE) for each sample location using an Application Programming Interface (API) developed in Python. Climate predictor variables were derived from the GRIDMET dataset and included daily cumulative and percent of 40-year normal precipitation and growing degree days (Abatzoglou 2012). Season long normalized difference vegetation index (NDVI) values were extracted for each clip plot pixel from the Sentinel-2 satellite imagery dataset. For each pixel, a cubic spline was fit and used to estimate daily NDVI values and the estimated NDVI for the day the plot was clipped was used as a predictor variable in the model. A multivariate random forest model was trained with ADF as the dependent variable and climate and satellite imagery metrics as the predictor variables. This model was then used to predict daily ADF values for each pasture.

Animal performance
Daily animal BW were measured using SmartScales™ technology (C-Lock Inc., Rapid City, SD, USA). Briefly, SmartScale™ is an in-pasture weighing technology that is placed in front of existing water tanks that measure animal BW while drinking by recording RFID tag data and front-end weight, which is converted to full BW through a linear transformation (Brennan et al. 2023). Spurious weights were removed from the dataset using robust regression technique (Parsons et al. 2023). For each individual animal, smoothing splines were fit with BW as the dependent variable and date as the independent variable. Smoothing splines models were then used to predict daily BW for each steer allowing for non-linear dynamics of animal growth. Daily ADG was estimated as the difference between modelled BW on consecutive days.

Dry Matter Intake Calculations
Individual steer growth performance and daily forage ADF determinations to were used to estimate the daily DMI required for gain. Briefly, a DMI function (DMI_{func}) was developed in program R. The DMI_{func} takes the inputs of ADF to estimate ME, initial BW (BW_t), final BW (BW_{t+1}), and days on feed to determine daily gain. Daily ADF values for each pasture were derived using the random forest model described above; BW_t and BW_{t+1} were derived from the smoothing spline model described above for each steer, with days on feed set to one in the function. Metabolizable energy was determined based upon estimating total digestible nutrients from ADF, and mathematically converting to digestible energy, metabolized energy, and forage net energy for maintenance and growth based on equations outlined in NASEM (2016).

Results
On average, estimates of DMI as a percentage of BW ranged from 2.39% to 2.80% over the entire trial period (Table 1). The daily estimate of DMI as a percentage of BW for each individual steer ranged from 1.19% to 10.86%. Averaged over the course of the grazing season, as a percent of BW, DMI estimates are well within expected ranges for grazing cattle. Daily estimates above 4.5% DMI as a percentage of BW represent 1.8% of all observations, and of those 53% occurred during the first and last week of the trial. This indicates that higher estimates of DMI are likely the result of the smoothing splines over estimating ADG at the beginning or end of the trial period, perhaps due to daily weight data being less sparse within these time frames.

In addition, for each grazing steer, we calculated cumulative DMI over the course of each grazing season (Figure 1). Cumulative estimates of DMI at the herd level ranged from 497 kg in the heavy graze pastures in 2022 to 967 kg in the light graze pastures in 2023. Differences in cumulative intake between years is likely driven by the number of grazing days and average herd BW. Results presented in Figure 1 can be used to estimate forage removal by grazing livestock and subsequently inform rotational grazing decisions when desired utilization has been reached.

Discussion
Estimating DMI for grazing cattle is difficult. Previous methods have utilized animal nutrition equations, forage clip plots, and forage marker techniques, all of which have their challenges that balance precision of

estimates, time and effort, and costs. For example, estimating forage disappearance with utilization cages can be used to estimate DMI at the herd level but fails to capture individual animal variability. Likewise, approaches that estimate DMI using animal nutrition equations rely on ADG estimates over monthly time frames and may not consider day to day variability of environmental conditions of the grazing animals (Undi et al. 2008). To our knowledge, this is the first attempt to estimate daily DMI for grazing beef cattle by integrating PLT to more accurately account for dynamic changes in forage quality and animal weight gain over an entire grazing season.

The objective of this paper was to demonstrate how technology and animal nutrition models could be integrated to make predictions on DMI for grazing cattle. Though this model considers daily estimates of forage quality and BW, other factors such as ambient temperature and forage availability can also impact DMI. Factors such as ambient temperature or heat stress equations could be incorporated into energy maintenance estimates to help refine predictions. In addition, these results can be used to determine the impact that stocking rate, rotational grazing patterns, or heat stress have on daily DMI and subsequent ADG to help optimize livestock production.

Often in the field of rangeland management, stocking rates are set based on average forage production, average herd BW, and a constant percentage of BW for estimating DMI. Given the high variability in forage production and quality between wet and dry years, this approach will likely miss grazing management targets within a given year as stocking rates often don't account for the dynamic nature of animal BW and forage quality. The objective of PLT is to utilize technology to generate real time data collection, which can be integrated into models to inform decision making allowing land managers to better hit their production goals either at the individual animal or herd level.

Table 1: Mean estimates of daily dry matter intake (DMI kg), DMI as a percentage of body weight (% BW), average daily gain (ADG kg/head/day), and acid detergent fiber (ADF) for steers grazing native range over 3 years at the South Dakota State University Cottonwood Field Station (Cottonwood, SD). USA).

Year	Stocking Rate	Daily DMI	% BW	ADG	ADF
2021	Heavy	9.62	2.39	0.79	32.17
	Moderate	10.95	2.69	0.88	34.21
	Light	10.32	2.57	0.82	34.23
2022	Heavy	7.66	2.39	0.65	33.06
	Moderate	8.00	2.73	0.75	34.29
	Light	9.30	2.58	0.76	34.31
2023	Heavy	10.27	2.59	0.91	32.37
	Moderate	9.92	2.72	0.88	33.76
	Light	11.26	2.80	0.89	33.89

Key words: State-and-Transition, Remote Sensing, Spatial applications

Abstract
Assessing vegetation conditions in expansive rangeland ecosystems has long posed a persistent challenge. Recent advancements in remote sensing technologies have provided new tools for improving this assessment process. In this study, conducted at two ranch sites in Nevada, we integrated existing line-point-intercept monitoring data with additional field observations to evaluate the vegetation condition or "State" at various monitoring points. We then employed machine learning techniques to classify gridded raster datasets, aligning them with existing State-and-Transition models (STMs) specific to each study area. Leveraging Landsat-derived fractional cover datasets, as well as climate and soil predictors, we aimed to predict vegetation State in specific land types. The resulting vegetation State maps were then combined to generate a cohesive representation of vegetation conditions across the study sites. Our analysis revealed that relative functional group cover emerged as a superior predictor of vegetation state and ecological processes at the site level. However, we encountered variations in state mapping accuracy ranging from approximately 14% to 44% error. These discrepancies were influenced by factors such as study location, landscape heterogeneity, availability of training data, and species-specific challenges, all of which complicate the accurate classification of remote sensing datasets.

Introduction
For over a century, understanding rangeland dynamics has guided rangeland management. Central to this understanding are state-and-transition models (STMs), which describe vegetation changes driven by ecological processes (Westoby et al., 1989; Stringham et al., 2001). However, applying these models across large landscapes remains challenging, as ecological sites—the foundational spatial units for STMs—often vary at scales too fine for practical management (Stringham et al., 2016). To address this, recent efforts have focused on aggregating ecological sites into broader units known as Disturbance Response Groups

(DRGs), enabling the application of remote sensing to ecologically similar areas (Stringham et al., 2016; Phipps & Stringham, 2024).

Advancements in remote sensing have improved the ability to quantify vegetation cover by functional group, providing a cost-effective alternative to extensive on-ground monitoring (Rigge et al., 2021; Allred et al., 2021). However, integrating remotely sensed data with STMs at landscape scales remains limited, as current datasets often fail to contextualize vegetation conditions relative to ecological site potential (Briske et al., 2006; Smith et al., 2023). Digital soil mapping offers a promising solution, correlating soil properties with ecological sites to enhance STM application (Nauman et al., 2022, Phipps and Stringham 2024).

This project aims to create spatially explicit STMs by combining remotely sensed vegetation data, soil mapping, and ground-based monitoring. The resulting framework provides land managers with a scalable, spatially informed tool for effective rangeland planning and decision-making. The workflow, illustrated in Figure 1, highlights the integration of vegetation cover, soil data, and iterative refinements to advance landscape-scale STM applications. Details of the methodology are outlined in subsequent sections.

Methods

Study Area:

This study focused on two Nevada ranches participating in the Bureau of Land Management (BLM) Outcome-Based Grazing Alternative (OBGA) pilot project, emphasizing ecological, economic, and social outcomes. The Winecup Gamble Ranch (northeast Nevada) and Smith Creek Ranch (central Nevada) were selected for their contrasting fire histories and ecological characteristics, as well as representation of major Western United Sates eco-regions. Together, the study areas spanned approximately 464,525 hectares.

Data Collection:

State-and-transition models (STMs) for land types which respond similarly to disturbance were developed using ground-based vegetation data from multiple sources, including BLM, NRCS, and University of Nevada research plots. Data were analysed using the Landscape Level Ecological Inventory and Assessment (LLEIA) database. Plots were classified into varying land types based on ecological site and DRG determinations. Wyoming Sagebrush plant community plots underwent detailed clustering and ordination using Principal Component Analysis (PCA) and Non-Metric Multidimensional Scaling (NMS) to define vegetation states, such as Shrub and Annual Herbaceous States.

Remote Sensing:

Vegetation cover data were derived from USGS RCMAP (2009–2021), incorporating variables such as shrub, tree, annual herbaceous, and perennial herbaceous cover, averaged over six years to normalize precipitation variability. Additional environmental predictors, including elevation, precipitation, soil pH, and reflectance indices, were integrated into analyses. Predictor variables were aligned to a 30m pixel size for consistency with Landsat imagery.

Data Analysis and Modelling:

Relative vegetation cover for functional groups was calculated for each plot. A Random Forest model was trained using extracted predictor variable values at plot locations to predict vegetation states across the study area. Iterative model refinement reduced error by eliminating low-importance variables. Final predictions were validated with plot photographs and mapped to represent vegetation states spatially.

Output and Applications:
The resulting vegetation state maps provide spatially explicit tools for rangeland management, highlighting ecological conditions and guiding decision-making at the landscape scale.

Results
A Random Forest model was used to classify vegetation states across study areas based on pixel-level predictions for each land type. Accuracy was assessed using withheld training data, yielding error rates from 14% to 44%, depending on the plant community. Error terms for each land type are summarized in Table 4. Key predictor variables included the relative proportion of shrub, annual herbaceous, and perennial herbaceous vegetation cover, while absolute cover metrics performed poorly. Final maps were generated by combining land type-specific classifications and incorporating pasture boundaries for enhanced visualization.

Key Findings by Land Type

- **Wyoming Sagebrush**: Largest extent and highest accuracy, with error rates of 13.8% (WGR) and 12.5% (SCR). Errors primarily occurred in rare states, such as the Current Potential State at SCR (66% error).
- **Low Sagebrush**: High error rates (44% WGR, 35% SCR) due to spectral similarity between dominant species (e.g., Sandberg's bluegrass) and cheatgrass.
- **Low Sagebrush (High Resilience)**: Predicted only at SCR with a 33% error rate, primarily in the Annual and Tree States.
- **Black Sagebrush**: Error rates of 24% (WGR) and 18% (SCR). The Annual State at SCR showed 100% error due to its rarity.
- **Mountain Sagebrush**: Errors were 21.4% (WGR) and 36.8% (SCR), influenced by terrain complexity and sparse observations of certain states.
- **Shadscale Saltbush/Bud Sagebrush**: Errors of 40% (WGR) and 28.6% (SCR). Shrub State was consistently accurate. Alternative states may not be present in the study sites.
- **Winterfat**: Sparse observations yielded error rates split across Shrub and Annual States.
- **Greasewood**: Modeled only at WGR with a 15.8% error rate, mainly between Annual and Current Potential States.

Figure 1 illustrates vegetation state maps for WGR and SCR, aiding management and monitoring. Detailed accuracy matrices for each VGG are provided in Figures 7–14.

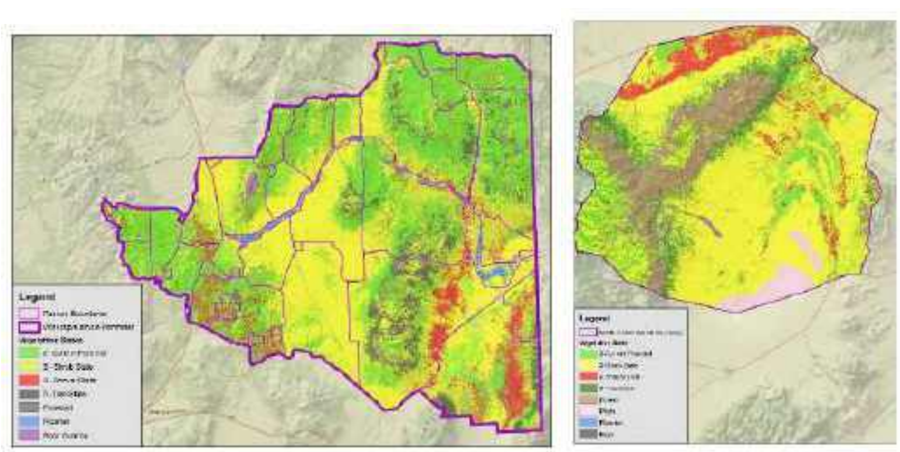

Figure 1: Vegetation state map of the Winecup-Gamble and Smith Creek Study areas. Showing states mapped across the management area, including pasture boundaries, to assist in management and monitoring decision making.

Discussion

This study highlights the effective application of fractional cover mapping technologies for spatially mapping vegetation states, adding a critical spatial dimension to State-and-Transition Models. This advancement enables practical management applications across scales, from pastures to regional planning, aiding proactive restoration and conservation efforts. It facilitates rapid assessment of areas that may have crossed ecological thresholds, requiring active restoration, or areas that could benefit from passive resilience-enhancing strategies.

While this analysis utilized vegetation monitoring data as training points, the approach can also work with visually assessed state conditions by experienced ecologists. Accurate soil and plant community mapping is essential, as plant community proportions vary significantly across these units. Relative cover emerged as a robust predictor of vegetation state, providing insights into the structural and functional dynamics of plant communities, outperforming absolute cover measurements.

The study focused on categorizing pixels into vegetation state categories to inform management priorities rather than tracking trends in vegetation cover or landscape outcomes. The RCMAP dataset effectively captured relative cover proportions, with perennial vegetation, shrub, and annual cover strongly predicting the Current Potential, Shrub, and Annual States, respectively. Climatic variables, including minimum and maximum temperatures and precipitation averages, further enhanced accuracy, particularly in the Wyoming Sagebrush land type, where they improved model performance by 7%.

Challenges remain in distinguishing areas seeded with agricultural cultivars, such as Crested Wheatgrass, from native perennial grass states. Secondary tools like the Monitoring Trends in Burn Severity dataset and the Land Treatment Digital Library can help identify seeded areas, though uncertainties persist due to historical mapping gaps. From an ecological perspective, these areas, while distinct in management context, may function similarly to native plant communities in terms of site dynamics.

Incorporating climatic variables and leveraging additional datasets can refine vegetation state mapping, providing greater precision for ecological assessments and management interventions, especially in expansive, heterogeneous landscapes like the Wyoming Sagebrush biome.

Acknowledgements

We would like to acknowledge the Fish and Wildlife Service of Reno Nevada for their generous contribution to make this research possible. We would also like to thank the ranches which served as an invaluable study area in this research. Without both these contributions, the research would not be possible.

Continental-scale modelling of pasture growth with the AussieGRASS model: Learnings from 30 years of operation

Carter, JO[1]; Bruget, D[1]; Stone, G[1]

[1] Queensland Department of the Environment, Tourism, Science and Innovation

Key words: Modelling, Pasture, AussieGRASS

Abstract

The AussieGRASS model has been run operationally for Australia since 1995, with modelling outputs of current conditions and forecasts provided each month to the Long Paddock website – and is considered an 'environmental calculator' rather than just a model of pasture growth. AussieGRASS was initially built to help quantify current conditions 'relative to history' to assist with drought and seasonal conditions assessment but has since been used for many additional purposes. There have been many challenges to building and maintaining 'the operational system' – some of these challenges are summarised in this paper with regard to: input data sets (historical and current climate, climate forecasts, tree density mapping, grazing pressure, land use etc); calibration and validation (integrating field and satellite observational data sets); computation (high performance computing and storage); extension (Long Paddock web site); and human capital (staff, collaborators, and management).

Introduction

The AussieGRASS system was developed using funding provided from the Land & Water Australia (LWA) Climate Variability Program in collaboration with other states (i.e. WA, NSW, SA and NT) to extend its application from Queensland to all of Australia. The driving forces and enabling mechanisms for its establishment were: the existence of the well-calibrated GRASP pasture growth model (Rickert et al. 2000), along with (SOI-based) climate forecast systems, and land degradation of Dalrymple shire which highlighted the need to track grazing pressure and pasture growth in 'near real time' (McKeon et al. 2004), and a review of drought and drought declaration policy in Queensland (Daly 1994). Modelled pasture growth typically provides a better indication of drought than rainfall alone, as runoff, soil evaporation and other climate elements (such as atmospheric moisture content) are accounted for in the simulations.

Initially, AussieGRASS was internally funded and run for Queensland only. Funding from competitive grants followed. The first of these grants allowed field validation activities for Queensland. Once operational, various States subscribed to the AussieGRASS system along with subscriptions to the SILO climate data system. This income sustained early development, however, downsizing of state agricultural departments and Queensland and interstate departmental reorganisations made it difficult to maintain subscriptions. In addition, a global move to offer 'open data' online, ultimately ended the subscription model. For most of the 30-year period the small AussieGRASS team has undertaken a range of short duration projects, including provision of data for three federal drought schemes, climate change impacts, net primary production comparison studies, estimates of biofuel potential of pastures, livestock methane production and rangeland monitoring (Bastin 2008). Maintaining the continuity of an operational AussieGRASS system given these challenges is discussed.

Systems development has been ongoing over three decades, with many ongoing improvements in software, data, algorithms, delivery platform and information technology. This paper describes some aspects of the 30-year AussieGRASS journey; whether programming innovations and data have stood the test of time – or in what direction, with the benefit of hindsight, the modelling might best have been progressed.

Model characteristics

The AussieGRASS model runs at a daily timestep, given most field measurements occur at this time scale (e.g. pasture biomass estimates) which allows modelled and field data to be matched in time and space. Remote sensing inputs are similar, in that most imagery can be matched with a model output on the same day. A monthly time step is considered too long, as some processes (e.g. runoff) occur at much shorter time scales and pasture growth in tropical regions can be rapid. Also, measured climate data at a sub-daily timestep are largely unavailable.

Historically a 0.05-degree grid (i.e. 5 x 5 km; 25 km^2) was considered optimal given computer capacity and spatial resolution of input data. It was important to define standards for coastline masks and rules for inclusion/exclusion of coastal pixels and to ensure precise alignment of independent input layers (climate, soils, tree density, fire, flood, grazing animal density). While input layers are used at 25 km^2, most were constructed at a finer 1 km^2 resolution to facilitate future higher resolution modelling. While the model is run daily at 25 km^2 resolution we recommend that users apply outputs such as pasture growth and other variables at about 10 to 30 times the spatial and temporal run resolution.

Development of climate data and other inputs

Climate data is perhaps the greatest challenge for modelling pasture growth, as plant growth models require a minimum set of daily input data. Ideally it is useful to be able to run the model back in time so comparisons with historical climate events (e.g. Australian 1901-1903 drought period and 1890s floods) can be made. Note, these historical events are still the most severe events experienced in some parts of Australia. It is also useful to examine the historical impacts of total grazing pressure on land degradation processes (e.g. McKeon et al. 2004). Quantitative drought evaluation to inform government policy necessitates a near real time supply of climate data for AussieGRASS model outputs. AussieGRASS evolved from ‘hand punching’ data to videotext and eventually internet File Transfer Protocol (FTP). Climate data interpolation algorithms and data quality control were implemented into the SILO system (Jeffrey et al. 2001). Gridded data sets were built and made available to the science community long before such data sets were available from the Bureau of Meteorology (BoM). The advantage of this ‘in-house’ climate data system is that it can be closely coupled to AussieGRASS in a shared computing environment where additional quality assurance analyses can occur. There is also the potential to add additional climate data to the system (especially rainfall). In recent times we have supplemented BoM rainfall data with rainfall observations from the Queensland flood warning network, as well as from our own network of about 30 grazing properties.

In addition to being able to run in ‘near real time’, the system needs to be able to re-run when additional rainfall data arrives in the system (especially from volunteers providing hard copy records). In Australia, data from only about 50% of rainfall stations are available in the first days of the new month, so the modelling system needs to be re-run and updated, typically four times a month. It is also useful to have climate forecast data at climate change and seasonal forecast time scales, as these forecasts combined with 'initial conditions' (typically soil moisture, nitrogen status and ground cover), can be used to estimate future pasture conditions.

Until recently, seasonal forecasts were generated from statistical systems that produced a set of 'analogue' years based on climate indicators such as the SOI. Analogue year systems are relatively easy to implement given access to a climate data archive. In the last decade or so gridded climate data from weather models has started to become available – and while these new data sources appear to be beneficial, they entail significant overheads as data needs to be bias-corrected and downscaled, automatically downloaded, resized to the user's grid dimensions and formatted.

Climate data quality and availability has declined since ~ 1970's due to a reduction in measurement sites. For example, both pan evaporation and cloud cover (a solar radiation proxy) have caused issues due to a lack of detection and slow switch over to satellite radiation estimates. Other important variables such as estimated total grazing pressure also present challenges as the Australian Bureau of Statistics (ABS) no longer collects annual agricultural statistics. Remote sensing is used for tree density inputs as well as fire scar data for biomass resets and the Landsat archive provides green and dry cover time series to assist model calibration.

Data formats and processing

An early decision in development of the AussieGRASS framework, derived from the group's experience in remote sensing, was to process data as raster grid cells rather than polygons. Initially we used formats from an older remote sensing package DSIMP but when this platform became obsolete, we developed our own data format designed to minimise storage and file upload time. A range of raster manipulation tools was developed inhouse for post processing (e.g. calculation of percentiles). While initially essential, this system has become limiting as NetCDF is becoming a global standard for climate and some ecological data. The SILO climate data is now produced in NetCDF format and the AussieGRASS model can input and output directly in NetCDF format, avoiding file conversion when using climate forecasts – in hindsight, a direction that could have been pursued much earlier.

The AussieGRASS model is highly optimised for a High-Performance Computing (HPC) environment and runs each pixel every day, reading and writing daily grids for the model extent rather than running each pixel for the duration of the simulation then moving to the next pixel which requires disassembly and reassembly of gridded input (especially climate data) and assembly of many small files to generate output maps. In the HPC environment efficient use of resources such as caching of input data in RAM disk rather than reading from spinning disk can reduce run times by more than 5%. There are very significant speed gains to be made in code optimisation. In particular, the layout of data in memory is critical in multi-threaded systems and memory access needs to be kept local to each thread. In addition, data arrays in memory need to be structured such that the next needed variables are close, so that caching is effective. We found that memory reorganisation could improve processing times by a factor of 8 or more.

Automation and diagnostics

Automation is essential especially when the system is run by a small team. The AussieGRASS operational system has been almost fully automated since inception. Model runs and post processing are instigated automatically. To deliver in 'policy' time often requires running on weekends and public holidays as well as having a system that copes with staff being on leave (with ability to remotely access the system). Despite automation, we believe it is important to have a minimum of 2-3 dedicated staff available to cope with any problems that emerge, monitor progress and fix issues. AussieGRASS has produced monthly outputs within a few days of the end of each month for about 30 years (with the longest outage being about 10 days due to a climate data system rebuild). Operations are designed to be largely fail-safe. For example, if the input data does not arrive there is a fall back to long-term average climate or secondary data sources.

The system produces many log files and emails signifying the success or otherwise of completed tasks. These often help to diagnose any potential problems. Furthermore, additional ancillary model outputs are generated such as plant nitrogen status for rapid diagnostic examination. Along with the biophysical model code, there is a large amount of coding that supports model calibration and validation. This calibration and validation coding and data preparation programming represents the bulk of the total coding effort in the modelling system (Table 1).

Modelling Outputs

Success in modelling relies on providing useful and accessible information. The Long Paddock website (Stone et al. 2019) has been the key delivery website and has evolved over time. We believe that it is a significant advantage to have a recognisable brand and web presence that is enduring, rather than being lost amongst ever changing general government web platforms. In addition, autonomous website control allows rapid updating and fixing of issues that would otherwise be someone else's low priority. Ability to rapidly produce test web pages within an operational environment and fully automated product uploads/reloads are essential. In the early stages of the AussieGRASS development we used a specialist extension officer to extend the AussieGRASS and the Long Paddock website across Queensland and Australia. In recent years there has been no major nation-wide extension effort, and we largely rely on users outside Queensland, finding their own way to the website. A key part of the websites success has been due to the team's efforts in marketing the Long Paddock product suite at field days and workshops.

The product package from AussieGRASS includes a range of grazing and fire related products typically made available as relatively simple to understand maps and tables. Products are made available in different formats such as PDF files, GeoTIFF, and text files and are named systematically such that automated retrievals of data from the web site are possible. Information is generated as actual amounts and percentiles (of various duration) to display current conditions relative to history. While many drought products use complicated indices, we have chosen percentiles as most likely to be understood by our general audience and we support the maps with a video explaining percentiles tailored to landholders. Perhaps the most challenging issue in regards percentiles is the most appropriate baseline period to use.

Results

As a regional to national scale product AussieGRASS remains useful after 30 years and currently contributes to the national AADI program (Hughes *et al*. 2025), revised Queensland drought analysis, daily calculation of fuel loads for fires and information for plague locust modelling. A 1 km resolution version of AussieGRASS that improves accuracy of tree-grass competition is in pre-production testing, as are climate change runs to 2100 with 3 scenarios and 15 models. Its companion product FORAGE, which is designed for paddock to property-scale application, uses the same data, pasture model, computing infrastructure and website with shared 'team effort', to generate about 50,000 property scale reports per year. The SILO climate data system continues to produce ready to use climate data for a large user community.

Discussion

There are many reasons for the success and endurance of the AussieGRASS product, however, the most important to us seem to be: (a) tight integration of the modelling system with climate and other data inputs and a web-based front end, all largely under a single supportive management structure; (b) strong focus on usable products that serve a variety of users; (c) systems designed for both broadscale and property applications; (d) concentration on gathering and using a broad range of calibration and validation data sets and (e) adequate base funding to maintain computing and data infrastructure and a small number of long serving staff who apply the skills of systems analysis to provide an operational and enduring service. Challenges remain, however, as continuing deterioration of climate monitoring and agricultural statistics, broad-scale species change (e.g. Buffel grass invasion) and lack of fire and woody density clearing maps pre-1980s all present formidable challenges.

Table 1. Characteristics of the AussieGRASS system.

Subject	Comment
Time Step	Daily to match satellite and ground measurements, aim to approach reality at monthly time scales, capture runoff and erosion events. Also, matches available climate data.
Calibration spin-up	Approximately 30 years to equilibrate pasture biomass especially for slow growing arid zone species (e.g. *Triodi*a spp).
Spin-up operational	Model is run forward from 1890; state variables are saved, then last 2-3 years are updated with each model run to ingest updated rainfall and climate data. Then forecasts are run with best estimates of initial conditions.
Calibration	PEST optimisation package and manual calibration (which may include many variables).
Output timing	Run at day 1-3 each month; update runs about every 10 days to capture updating rainfall data, daily for fuel loads.
Output variables	Most model variables can be output if desired, input variables for checking, absolute values, counts > threshold.
Output method	Data grids for daily, monthly, annual, selected date, to match observations, ascii files to match single point observation, various diagnostic tables for running in single pixel mode.
Data formats	Internal Drought Research Raster (in-house, binary run length encoded), NetCDF. Outputs GeoTIFF, PDF, ASCII tables. (maps with colour blind and other accessibility features)
Post processing	Percentiles of various durations; monthly to 30 years, maps, time series plots, probabilities, anomalies.
Automation	Linux 'cron' automation utility starts (various model runs, fuel loads, 1 km experimental, several seasonal forecasts, post processing to percentiles, map generation, archiving, placement on Long Paddock).
Time duration	1880-1890 spin-up, 1890-today, 3 months ahead, standard 18 months ahead for both weather model climate and statistical forecasts. 1975-2015 climate change baseline, current to 2100 for climate change.
Spatial resolution	Projection geographic, 5 km version (pixel size 0.05 degrees; grid extent -10^{0}S, -44^{0}S; 112^{0}W, 154^{0}W) and 1 km version (pixel size 0.01 degrees; similar grid extent).
CO_2 effects	Can be fixed concentration, historical timeseries, or represent CO_2 associated with climate change forecasts (i.e. Shared Socioeconomic Pathways).
Climate inputs	Daily rainfall, Tmax, Tmin, vapour pressure, solar radiation, potential evaporation (wind optional).
Additional inputs	Fire scars (1-3 days), total grazing pressure (annual, 6 animal types), floods from Landsat water masks, ocean mask.
Satellite calibration/validation	(Initially NOAA AVHRR NDVI) Landsat main source of calibration data (all scenes in Australia for fractional green and total cover), ancillary; GRACE soil moisture, OCO_2 chlorophyll fluorescence, CO_2, Scimachy CH_4, AMSR surface soil moisture, Sentinel 1 G0 backscatter for soil moisture., ERS2 radar altimeter backscatter.
Site based calibration /validation	TSDM > 600,000 observations, pasture N concentration, soil nitrate, soil moisture, pasture utilization, grass basal area, live weight gain, erosion, runoff, tree litter fall and mass, grass litter, grass root mass, ground cover, pasture growth.
Inputs static	Soils type and soil parameters, pasture community map, tree density map.
Coding	Main model code Fortran 90 (~ 31K lines), post processing shell scripts and plotting (R), python, (~17K lines). Data preparation e.g. total grazing pressure (shell, python, Fortran 90 (> 85K lines), calibration/ validation, etc (> 172K lines)

Abstract

The use of on-animal sensors to manage and monitor free-ranging livestock has advanced rapidly over the past decade, particularly with the emergence of virtual fencing technology to manage livestock distribution. Low-cost GPS tracking for purposes of virtual fencing creates new opportunities to monitor animal health and behaviour when combined with an accelerometer to quantify the animal's behavioural state. However, our understanding of how behaviors can be quantified via GPS plus accelerometer measurements, and how foraging behavior metrics relate to diet quality or animal growth rate remains in its infancy. Here, we provide an overview of multiple studies that use on-animal sensors to quantify daily foraging behaviour of both yearling steers and mature cows in semi-arid rangelands of central North America (Colorado and Wyoming). We examine analyses of behaviour at varying time steps (seconds to minutes) summarized over the daily cycle using both commercially available and custom-built GPS plus accelerometer combinations. Foraging behaviour could be most accurately predicted by analyzing both sensors at a time step of 90 seconds, but an accelerometer algorithm calculated at a 30-second time step could be linking to longer GPS fix intervals with nearly equivalent prediction accuracy. We then focus on the utility of three key behavioral metrics: (1) mean daily grazing bout duration (GBD), (2) mean velocity while grazing (VG), and (3) the tortuosity of grazing pathways quantified as the mean turn angle while grazing (TAG). Our analyses identify GBD and VG as key indicators of declining forage availability, which could be used to guide the timing of pasture rotations or provision of supplemental feed. Furthermore, VG and TAG are significantly affected by stock density (herd size relative to pasture size), and hence could potentially be used to identify a threshold density that inhibits selective foraging and reduces weight gain.

Introduction

On-animal sensors are increasingly used to monitor and manage livestock in intensive production systems, but have received less attention in extensive rangeland settings (Trotter et al. 2019). However, the emergence over the past decade of virtual fencing technologies that rely on GPS tracking of individual animals creates new opportunities to monitor animal health and foraging behaviour in extensive settings where managers do not have frequent visual checks of their livestock. Advancing the effective use of on-animal sensors in extensive settings will rely on understanding how GPS tracking and behavioral sensors such as accelerometers can be combined to quantify animal foraging behaviors, developing durable and cost-effective sensors and associated attachment to animals, and developing of cost-effective means to transmit sensor data to managers (Bailey et al. 2018). Here, we provide an overview of multiple studies that have used on-animal sensors to quantify daily foraging behaviour of both yearling steers and mature cows in semi-arid rangelands of central North America (Colorado and Wyoming). We examine (1) accuracy of calibrations of grazing, walking and stationary activities using varying models of devices, (2) use of resulting predictions to quantify metrics of daily foraging behaviour, and (3) how these foraging behaviour metrics vary in relation to factors such as forage allocation and quality, and paddock and herd size.

Methods

We first compare predictions of cattle (*Bos taurus*) activity states (grazing, walking, stationary) using (1) commercial GPS tracking collar with a 2-axis activity sensor (Augustine and Derner 2013), (2) commercial GPS tracking collar with a 3-axis accelerometer (Augustine et al. 2023), (3) in-house constructed collar with off-the-shelf GPS and 3-axis accelerometers (Cunningham et al. 2024), and (4) commercial GPS tracking ear tag with 3-axis accelerometer. All devices were capable of collecting GPS fixes at 5-min intervals. The in-house collar collected GPS fixes at 1-second intervals, allowing us to rarify the data to varying epoch lengths (e.g. 10 sec to 15 min), and examine the optimal length for prediction of activity states via GPS+accelerometer or accelerometer alone. The eartag device was the xTPro produced by 701x (Fargo, ND, USA; 701x.com). We fitted xTPros on 69 yearling steers (23 in each of 3 different pastures) at the Central Plains Experimental Range in northeast Colorado during May – Sept of 2024. The 3 study pastures differed in stocking rate (low, moderate and high), and in vegetation composition, where the light stocking pasture was dominated by C3 midgrasses, and the heavy stocking pasture dominated by C4 shortgrasses (Porensky et al. 2017). We conducted direct observations of behaviours of 24 different steers wearing these eartags during May – July of 2024, where activity (grazing, walking, stationary, other) was recorded at a 30-second time step as described by Cunningham et al. (2024). The eartags collected GPS fixes at 5-min intervals, and used a 3-axis accelerometer in combination with a proprietary algorithm to predict the number of seconds in each interval the animal was grazing, walking, stationary (sum of resting and ruminating), or unknown. We classified each 5-min interval based as whichever activity occurred for >=50% of that interval, based on both direct observations and eartag predictions. Intervals in which no single activity occurred for >=50% of the time were classified as mixed.

We compared metrics of foraging behaviour from three studies that deployed (1) GPS collars with a 2-axis activity sensor (Lotek 3300LR) on yearling steers grazing shortgrass rangeland (data from Augustine et al. 2023), (2) GPS collars with a 3-axis accelerometer (MOOnitor.com) on yearling steers grazing shortgrass rangeland (data from Augustine et al. 2022), and (3) GPS collars with a 3-axis accelerometer (MOOnitor.com) on 12 mature cows with calves within a herd of 120 pairs grazing mixedgrass rangeland in northeastern Wyoming. In the latter study, collars were deployed during the 2021 growing season, with GPS fixes at 5-min intervals. Collared cows and their calves were individually weighed at the beginning and end of July, when vegetation was greening up and near peak biomass, and again at the beginning and end of September, when vegetation was senescing and reduced in biomass. We used data from the collars to calculate mean daily velocity while grazing (VG, in m min^{-1}), mean daily grazing bout duration (GBD, in min) and mean daily turn angle while grazing (TAG, in degrees measured as deviation from a straight line), following the same methods as Augustine et al. (2022).

Results

Table 1. Comparison of different on-animal sensors for their efficacies to predict cattle grazing and other activities for yearling steers grazing shortgrass rangeland in northeastern Colorado. Activity categories are G = Grazing, NG = Not Grazing, W = Walking, S = Stationary, and M = Mixed. Data sources are [a]Augustine and Derner (2013); [b]Augustine et al. (2022); [c]Brennan et al. (2021), [d]this study, [e]Cunningham et al. (2024).

Sensors	Attachment	Model	Timestep	Activity categories	Misclass Rate	Source

Predictions of cattle grazing activity via different on-animal sensors

Misclassification rates for cattle activity were lower when making binary predictions of grazing vs. non-grazing activity, compared to predictions of four activity classes (grazing, walking, stationary, and mixed; Table 1). When distinguishing between all four activity classes, misclassification declined from 16-18% using GPS with an activity sensor at 5-min intervals, to 10-13% using accelerometer data at 90-sec intervals. Misclassification rates were similar for GPS plus accelerometers mounted on an eartag, compared to the same type of devices mounted on a collar.

Variation in daily foraging behavior quantified via on-animal sensors

Mean daily velocity while grazing, grazing bout duration, and turn angle while grazing all varied in relation to forage conditions, stock density, and animal type. For yearling steers, a reduction in forage quantity and quality that reduced ADG from 1.11 to 0.25 kg steer-1 day-1 (HQl, HQt vs. LQl, LQt in panels A,D,G) also reduced VG by >2 m min-1, increased GBD by >80 minutes, and reducted TAG by 8 degrees. For yearling steers, a 10-fold increase in stock density (which reduced ADG by 15%) was associated with a reduction in VG by 1.5 m min-1, an increase in GBD by 10 min, and a reduction in TAG by 6 degrees.

Discussion

Rangeland scientists have long recognized that foraging behaviours are likely to reflect variation in feed intake and the quality of herbage eaten, and hence could serve as indicators of animal growth rates (Stobbs 1973, Chacon et al. 1976, Carvalho et al. 2015). Today, the increasing deployment of GPS collars on cattle for purposes of distribution management via virtual fencing creates opportunities to additionally monitor animal foraging behaviour via the addition of other sensors such as accelerometers. A synthesis of studies calibrating these various types of GPS + accelerometer combinations to predict cattle grazing activity at time steps of 1.5 to 5 min shows that misclassification rates of less than 15% can be achieved, both with collar- and eartag-mounted devices, even when non-grazing activity is separated into stationary vs. walking vs. mixed categories.

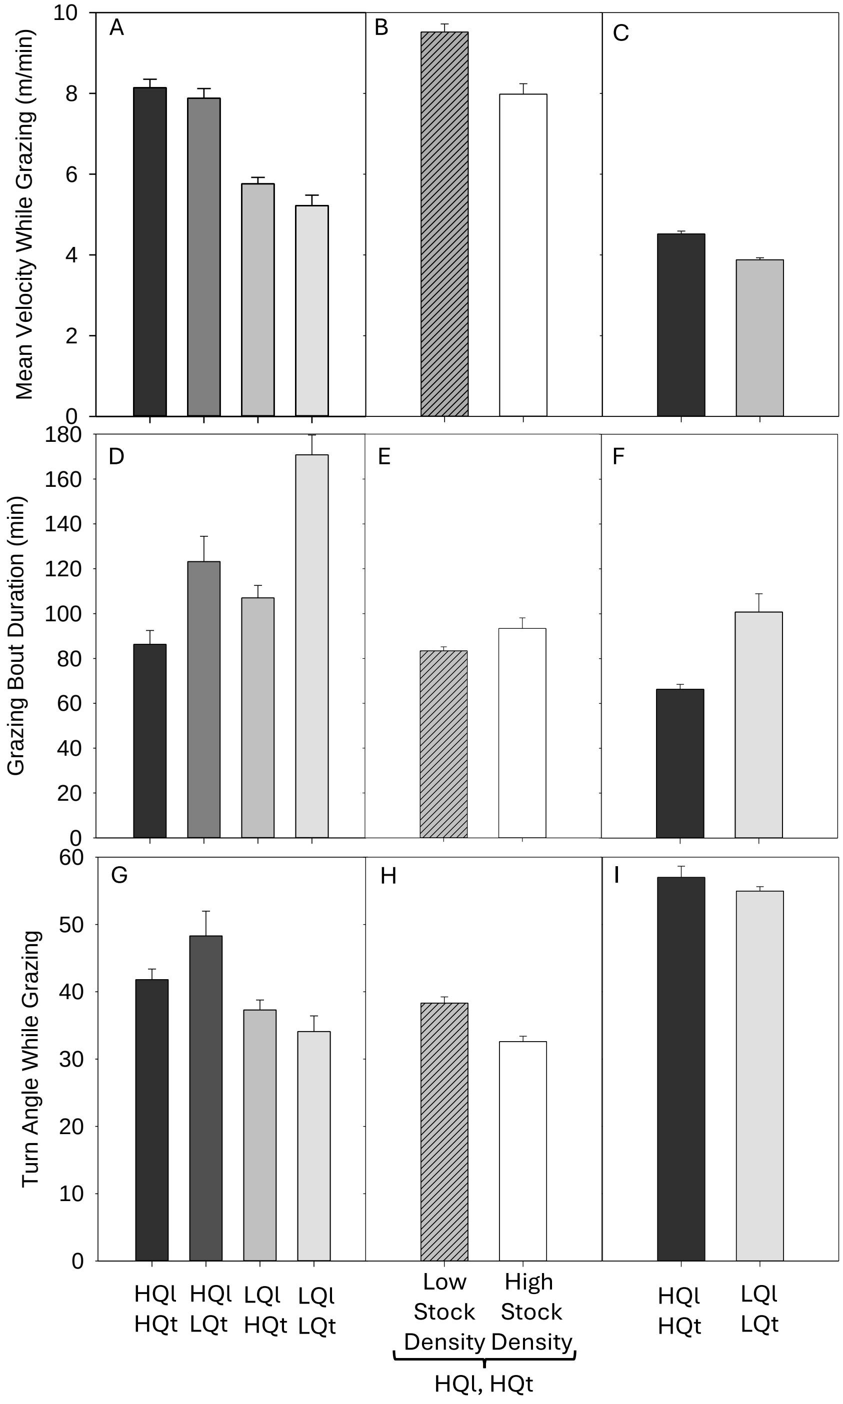

Figure 1. Comparison of three daily foraging behavior metrics quantified for free-ranging cattle in the semi-arid western Great Plains of North America using GPS collars combined with a 3-axis accelerometer. Panels A,D,G show results for yearling steers grazing shortgrass rangeland paddocks with varying forage conditions in 2020 (Augustine et al. 2022). Panels B,E,H show metrics for yearling steers grazing shortgrass rangeland with the same forage conditions early in the 2017 growing season, at high vs. low stock density (1.9 vs. 0.19 steers/ha; Augustine et al. 2023). Panels C,F,I show results for mature cows with calves grazing mixedgrass rangeland with varying forage conditions, quantified via MOOnitor

collars (GPS+3-axis accelerometer at 5-min intervals; this study). HQl = high quality forage; HQt = high quantity forage, LQl = low quality forage; LQt = low quality forage. Error bars show +1SE.

A key question is how to use these types of data to quantify foraging behaviour, and whether such behavioural metrics vary in response to foraging conditions and grazing management practices in predictable ways (Orr et al. , Carvalho et al. 2015). When we focused on 3 behavioural metrics calculated from collar data at a daily timestep (VG, GBD, and TAG), we found that VG is especially sensitive to both changes in forage conditions and management of stock density, both for yearlings and mature cows, in a way that reflects variation in cattle weight gain. Furthermore, VG was nearly equally sensitive to changes in forage conditions (both for steers and cows) as to a 10-fold increase in stock density. In contrast, TAG was more sensitive to changes in stock density, and GBD was more sensitive to changes in forage conditions. Findings also indicate that lactating cows graze at lower velocity and shorter GBD than steers for any given set of forage conditions, and cows exhibited more tortuous grazing pathways (greater TAG) compared to steers. As technologies for on-animal sensors to track foraging behaviour continue to advance and become more cost-effective, we encourage comparisons of consistent metrics such as VG, GBD, and TAG across varying rangeland conditions, animal breeds and age classes, and management regimes to develop a framework for real-time monitoring of animal condition and growth rates.

Cattle daily movement distance & habitat selection relative to production stage, phenotype, and demographics in northern Great Plains rangelands

Hennig, JD[1]; Scasta, JD[2]; Beck, JL[2]; Hill, JD[3]; Stam, B[2]

Key words: cattle, phenotypic variation, movement, production stage, step-selection

Abstract
Within a group of phenotypically homogeneous cattle, there may be genotypically driven individual variation that can influence daily movement patterns of cows. This suggests that individual animal selection is a potential strategy to improve grazing distribution in complex rangelands. In North America, there have been industry trends for larger and black-hided beef cattle yet there is limited information about how sized and colour influence movement rates and habitat selection. Annual production stages may further influence cattle movement due to time-varying nutritional and physical demands on reproductive females. To better understand beef cattle movement ecology, we placed GPS collars on multiparous Angus beef cows at the Padlock Ranch in Montana and Wyoming, USA to understand how daily distance travelled and habitat selection differed among age classes, body sizes, hide colour, production stage, and temperature. Daily travel distance was shortest during the mid-gestation stage, and greatest during breeding. We found interactions between temperature and both hide colour and production stage. Red cattle moved more during colder temperatures and cows moved more during late-gestation, lactation, breeding stages as temperature increased. Larger cattle selected greater herbaceous cover and forage production in most stages and closer proximity to water during lactation. Additionally larger cattle selected steeper slopes during breeding. Younger cows selected greater heat loads during late-gestation and lesser heat loads during breeding. Older cows also selected gentler slopes during breeding and weaning. Together, our findings provide information to livestock managers regarding individual characteristics that could be advantageous to their operation and may inform adaptive grazing management practices. Black hided cattle may be better suited to northern latitudes due to higher solar radiation capture. Larger cattle consume more forage but evidence of steeper slope selection during part of the year may offer trade-offs between feeding efficiency and distribution.

Introduction

Global Position System (GPS) technology has revolutionized animal movement research with important applications for livestock research and management on extensive rangelands. Such rangelands can be characterized by topographical heterogeneity and hydrological variability and consequently may constraint livestock distribution (Holechek et al. 1989). Within a group of phenotypically homogeneous cattle, individual genotypic variation can influence daily movement patterns of cows (Bailey et al. 2004). This suggests that individual animal selection is a potential strategy to improve grazing distribution in complex rangelands.

In North America, there has been an industry trend towards larger beef cattle due to the selection for genetic growth traits (Johnson et al. 2010). Concomitantly, there has also been an increase in the proportion black-hided beef cows. Larger cattle consume more forage and hide colour can influence thermoregulation (Scasta 2021), but there is limited information about industry trends relate to interactions between the animals and their environment. Research indicates that moderately sized cows may be more efficient or profitable than larger cows (Davis et al. 1994; Scasta et al. 2015) but we lack sufficient understanding about the size influences slope use or proximity to water. Additionally, as animals deal with dramatic seasonal temperature variation and escalating extremes due to climate change, an understanding of movement ecology in the context of hide colour becomes increasingly important (Shepard and Maloney 2023).

Annual production stages, including breeding, gestation, lactation, and weaning, may further influence cattle movement. These stages correspond with different nutritional and physical demands on reproductive females (Burns et al. 2010). Importantly, late-gestation and early-lactation, sometimes referred to as the "transition" stage, have significantly higher nutritional requirements due to the rapid foetal growth followed by the demand for lactation post-parturition (Lean et al. 2014). Thus, to better understand beef cattle movement ecology, we used GPS collars data to assess how daily distance travelled and habitat selection differed among age classes, body size, hide colour, production stages and ambient temperature.

Methods

We placed 40 GPS collars (Vertex Lite-2D Iridium collars, Vectronic Aerospace; Berlin, Germany) with a 2-hr fix rate on multiparous Angus beef cows (*Bos taurus*) in late-November to early-December 2018 at the Padlock Ranch along the Wyoming-Montana border. Cattle were collared for 3 years unless individuals were selected to be removed from the herd earlier. We deployed GPS collars on cows stratified across 4 management units and selected 10 cows per unit, with 5 red and 5 black cows in each unit. We selected study individuals to obtain variation in body size (hip height) and cow age. We classified production stages as mid-gestation (6 Dec–14 Feb), late-gestation (15 Feb–15 May), lactation (15 May–19 Jul), breeding (20 Jul–30 Sep), and weaning (1 Oct–5 Dec) based on information provided by the ranch manager. We calculated daily distance travelled by calculating the distance moved between successive GPS fix and then summing the resulting distances across each day. We obtained the mean ambient temperature experienced per cow per day using the air temperature sensor readings from the GPS location fixes.

We modelled daily distances travelled with generalized linear mixed models incorporating a lognormal distribution and a log link function. In all models we included year and management unit as fixed effects and a random intercept of individual ID to account for repeated measurements. We assessed models including fixed effects of production stage, hide colour, age, and hip height, along with interactions between each pairwise combination. Additionally, we assessed models with temperature, and interactions between temperature and production stage, colour, age, and hip height.

We used an integrated step-selection analysis (iSSA) to assess cattle habitat selection as they moved across the landscape. We fit individual iSSA models (Avgar et al. 2016) to each cow by year by production stage combination. Each model included 7 environmental covariates: heat load index (HLI), slope, topographic position index (TPI), proportion of herbaceous cover, distance to water, forage production (NDVI), and forage quality (instantaneous rate of green-up [IRG]). We used inverse-variance weighted regression to summarize selection responses at the population level and to test for differences in cattle age, hide colour, and body size.

Results

Daily Distance Travelled

The mean daily distance travelled per cow was 3016.65 m (SE = 9.98). Daily distance travelled varied by production stage with the shortest average distance occurring in mid-gestation, then increasing during late-gestation and lactation, before peaking during breeding and decreasing during weaning. Post-hoc comparisons revealed significant differences between each production stage. We found no significant differences among hide colour, age, and hip height; however, we discovered interactions between production stage and both age and hip height. Distance travelled decreased with age during mid-gestation and weaning, but increased during late-gestation, lactation, and breeding seasons. Daily distance travelled decreased with greater hip height during mid-gestation, lactation, and weaning, and increased during late-gestation, but did not differ during breeding. Black cattle moved less during mid-gestation, late-gestation, and weaning. We found no significant interactions between age and colour or hip height nor colour and hip height.

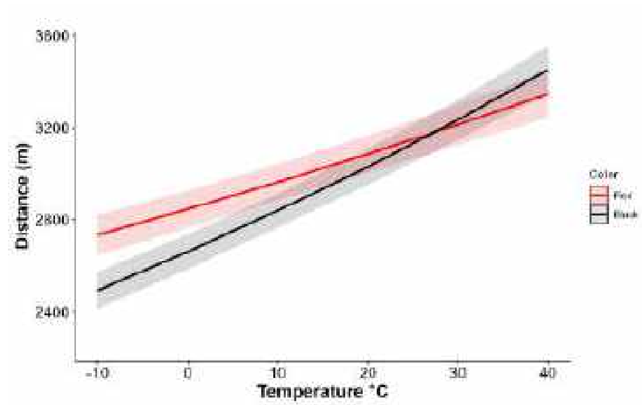

Figure 1. Average daily travel distance as a function of hide colour and ambient temperature, Padlock Ranch, Montana/Wyoming, USA, 2019–2021.

Daily distance travelled significantly increased with temperature. We found an interaction between temperature and colour with red cattle moving more during colder temperatures (Fig. 1). We also found an interaction between temperature and age with the oldest cows moving more than the youngest cows during the hottest periods. Lastly, we found an interaction between temperature and production stage with cows moving significantly more during late-gestation, lactation, breeding stages as temperature increased, but no difference during mid-gestation and weaning (Fig. 2). We found no interaction between temperature and hip height.

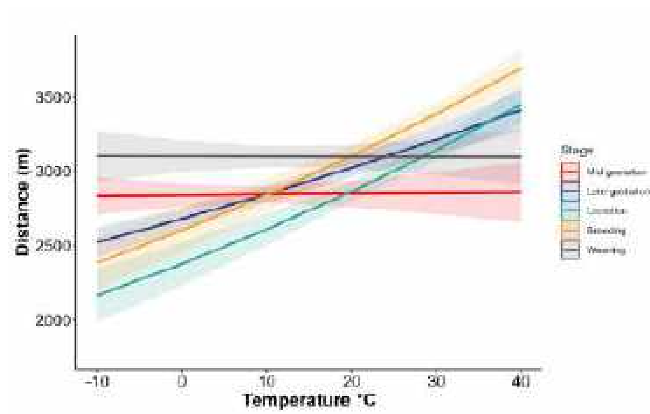

Figure 2. Average daily travel distance as a function of production stage and ambient temperature, Padlock Ranch, Montana/Wyoming, USA, 2019–2021.

Habitat Selection

Across all production stages, cattle selected greater herbaceous cover, gentler slopes, closer proximity to water, and lower topographic positions (e.g. low-lying areas). Selection for heat loads changed between the colder (mid- and late-gestation) and warmer (lactation, breeding, weaning) periods with cattle selecting greater heat loads during cold periods and lesser heat loads during warmer times. Cattle selected less vegetation production in mid-gestation and lactation but greater production during breeding. Year-round, cattle selected vegetation patches offering lower forage quality. Larger cattle selected greater herbaceous cover during mid-gestation and breeding, greater overall vegetation production during weaning, and closer proximity to water during lactation (Fig. 3). Additionally larger cattle selected steeper slopes during breeding. Younger cows selected greater heat loads during late-gestation and lesser heat loads during breeding. Older cows also selected gentler slopes during breeding and weaning (Fig. 4).

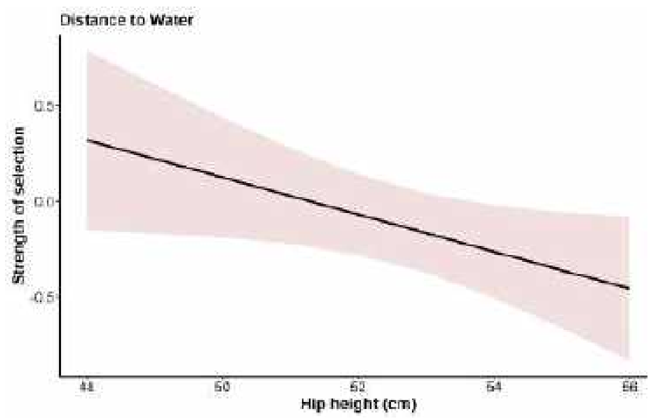

Figure 3. Strength of selection for distance to water during the lactation production stage as a function of cattle size (hip height), Padlock Ranch, Montana/Wyoming, USA 2019–2021. More negative values indicate stronger selection for closer proximity to water.

Discussion

We found that beef cow production stage, hide colour, age, and size can influence beef cattle daily travel distances or habitat selection in northern Great Plains rangelands. Production stage and temperature had the largest influences on daily distances travelled. Beef cattle managers should anticipate greater daily movements during breeding and weaning compared to mid- and late-gestational periods. Cows moved more per day with increasing temperatures during the warmest periods (late-gestation, lactation, and breeding). Longer travel distances during hot periods may be necessary to balance foraging arenas, shade, and water which can be disparately located across the landscape. Red-hided cows moved more than black cows during the coldest periods, perhaps to help with thermoregulation. We did not have data to equate

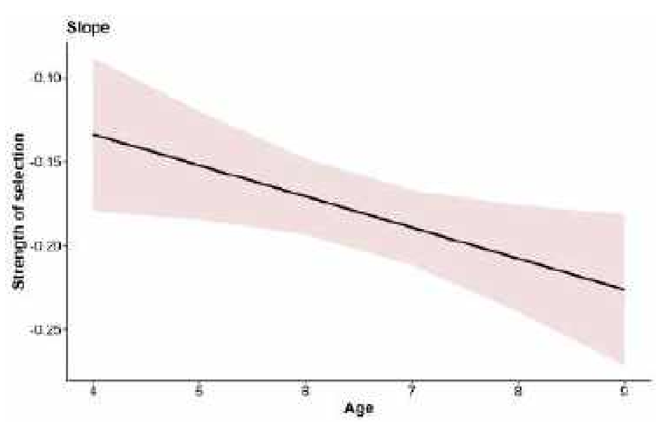

Figure 4. Strength of selection for slopes during the weaning production stage as a function of cattle age, Padlock Ranch, Montana/Wyoming, USA 2019–2021. More negative values indicate gentler slopes.

daily movement distances with energy expenditure or daily weight gains, but black cattle may be better suited to this region due to higher solar radiation capture (Scasta 2021).

We found seasonal differences in habitat selection based on cow age and body size. Younger cows selected cooler areas during the hottest time of the year (breeding) and warmer areas during the coldest period (mid-gestation), thus they may not yet be fully accustomed to this environment. Older cows more strongly avoided steeper slopes during breeding and weaning, which may be attributed to less vigour than younger animals at the end of the annual cycle. Outside of the most energetically demanding periods stages (late-gestation and lactation), larger cows likely consumed more forage evidenced by greater selection of herbaceous cover and vegetation production. Moreover, larger cattle used areas closer to water during the lactation period, perhaps to compensate for increased lactation demand relative to smaller individuals (Prichard and Marshall 1993). Together, our findings provide information to livestock managers regarding individual characteristics that could be advantageous to their operation and may inform adaptive grazing management practices. Regarding industry trends, black hided cattle may be better suited to northern latitudes with long and cold winters where heat transfer between an organism and its environment can be influenced by the difference between the surface temperature of an organism and the temperature of the surrounding environment (Scasta 2021). Conversely, lighter coloured individuals may be better situated to deal with extreme heat in more southern locales, although this has yet to be tested. Larger cattle ostensibly eat more but we also found evidence that they select steeper slopes during part of the year, thus there may be trade-offs between feeding efficiency and distribution. Lastly, younger cattle appeared to be less habituated to the thermal extremes of the environment but were more willing to use steeper slopes, again offering a trade-off for managers.

Abstract

Healthy land is a prerequisite for sustainable development and human well-being. With high levels of biodiversity and provision of critical ecosystem services, rangelands support 50% of the world's livestock and over 2 billion people. Rangeland degradation thus represents a major global challenge with severe negative impacts on biodiversity, climate change, and water and food security, affecting the livelihoods of millions of people. In the drylands of East Africa, these challenges are particularly acute. Halting rangeland degradation and restoring degraded land is thus essential in safeguarding ecosystem services and ensuring human well-being. Understanding the dynamics and patterns of rangeland degradation is critical for guiding restoration efforts to achieve positive and sustainable outcomes.

Here, we present results from systematic assessments of soil and land health conducted across contrasting rangeland landscapes in East Africa using the Land Degradation Surveillance Framework (LDSF). We conducted assessments of vegetation diversity, with an average of 15 perennial grass species per 100 km^2 LDSF site. The results indicate contrasting land degradation dynamics among and within the different sites. We applied Earth Observation in combination with field and lab data collected using the LDSF to produce high-accuracy predictive maps of different biophysical indicators, including soil organic carbon and soil erosion. The maps of soil and land health indicators showed clear spatial patterns across the landscapes. These results demonstrate the importance of simultaneously assessing multiple indicators of soil and land health and their interactions. We also present results from our work in four 'Livestock Cafés' in the cross-

border area between northern Kenya and Uganda. Livestock Cafés are experimental sites and knowledge-sharing hubs where we are engaging with local stakeholders to test and demonstrate innovative land restoration options for enhanced fodder production and regenerative kitchen garden development for improved food and nutrition.

Introduction

Rangelands cover an estimated 50% of the world's land area and provide a wide range of ecosystem services, including habitat provisioning, carbon sequestration, and food and water supply (Briske, 2017; UNCCD, 2024). However, interlinked land degradation, climate change, and biodiversity loss crises threaten rangeland ecosystems, jeopardizing the provision of these vital ecosystem services and the livelihoods and well-being of the people they support (IPBES, 2018; IPCC, 2019; UNCCD, 2024). In East Africa, rangelands constitute the dominant land use system, covering vast areas of land and supporting the livelihoods of millions of pastoralists (ILRI, 2021). Here, widespread rangeland degradation, climate change, and biodiversity loss constitute significant social-ecological challenges. These crises are mutually reinforcing; climate change is a principal driver of land degradation and biodiversity loss, while land degradation and biodiversity loss further accelerate climate change (IPBES, 2018; IPCC, 2019). Halting land degradation and restoring degraded rangelands is critical to reverse these negative trends (IPBES, 2018). Kenya, Uganda, and Tanzania have pledged to restore millions of hectares of degraded lands in the coming years, and many of these commitments specifically target rangelands. Understanding the dynamics and patterns of rangeland degradation and tracking the impact of restoration interventions is crucial for guiding such restoration efforts to achieve more positive and sustainable outcomes.

Here, we present some preliminary results and experiences from the research project Restore4More (2024-2027). The entry point of Restore4More is to identify the synergies in the biodiversity-water-climate nexus to accelerate the restoration of degraded rangelands for enhanced climate change adaptation and mitigation, biodiversity, and water and food security in the drylands of East Africa. We conducted systematic assessments of soil and land health across five rangeland-dominated landscapes in northern Kenya and Uganda with the aim of understanding the dynamics and patterns of land degradation across these sites to guide the planning and implementation of restoration interventions. We show key findings from these assessments, some examples of rangeland restoration interventions co-designed and implemented with local communities in knowledge-sharing hubs, and how we monitor restoration activities through an innovative approach combining field and lab data, Earth Observation and assisted citizen data collection.

Systematic assessments of land and soil health

We systematically collected data on soil and land health indicators across five rangeland-dominated sites in the cross-border area between northern Kenya and Uganda using the Land Degradation Surveillance Framework (LDSF) (Vågen & Winowiecki, 2023). *Chepareria, Lokiriama,* and *Kalama* sites were located in West Pokot, Turkana, and Samburu counties (Kenya), respectively, while *Matany* and *Rupa* sites were located in Napak and Moroto districts (Uganda).

Indicators measured included soil organic carbon (SOC), soil infiltration capacity, erosion prevalence, vegetation structure, tree density and species diversity, herbaceous cover and species diversity, soil texture, and pH. A total of 778 plots were sampled across the five LDSF sites. Plots (1000 m^2) were nested within clusters (1 km^2) and clusters within sites (100 km^2), following a hierarchical sampling design. Further details on the LDSF methodology, including the field sampling protocols and analysis of soil samples, can be found in Vågen and Winowiecki (2023).

Lokiriama and *Kalama* had the highest woody cover, with an average density of woody plants (trees and shrubs) of 275 and 243 individuals ha^{-1}, respectively, whereas in *Matany*, the average density was only 18 individuals ha^{-1}. Species richness was highest in *Chepareria* (50) and lowest in *Matany* (10). In *Lokiriama* and *Rupa*, nearly 50% of the sampled trees belonged to a single species - *Acacia reficiens* and *Acacia mellifera*, respectively. Tree species diversity was also low in *Matany*, whereas *Chepareria* had the highest diversity of trees, including several species that are important sources of fodder, food, and fuelwood. *Chepareria* was also the site with the highest richness of perennial grass species (37), whereas *Lokiriama* was the lowest (16).

Soil erosion is a major problem in the Kenyan sites (*Lokiriama, Kalama,* and *Chepareria*), where severe erosion was detected in 50-100% of the plots per cluster. In contrast, only a few plots presented severe erosion in *Matany* and *Rupa* (Uganda). Median topsoil organic carbon (SOC) content was lowest in the *Kalama* and *Lokiriama* sites (3.6 and 4.6 g kg^{-1}), whereas in *Matany* and *Rupa*, it was nearly threefold. The differences in SOC among sites were partly explained by differences in soil texture, with more fine-textured soils with higher clay content in *Rupa* and *Matany* sites compared to the rest. Saturated topsoil hydraulic conductivity, which controls the soil infiltration capacity, was relatively low in all five sites, with median values ranging between 10 mm h^{-1} in *Chepareria* and 60 mm h^{-1}in *Matany.* There was a clear negative relationship between erosion prevalence and soil infiltration capacity, especially for soils with higher clay content. This hints at a critical self-reinforcing feedback loop that amplifies land degradation: soil degradation and reduced infiltration capacity lead to more surface runoff and erosion, which in turn lead to further land and soil degradation and reduced infiltration.

Results from this assessment indicate contrasting land degradation dynamics among and within the different sites. For example, In *Lokiriama*, the encroachment of the invasive *Acacia reficiens* is a major problem and soil erosion was widespread. In contrast, Chepareria had severe erosion despite no signs of woody encroachment and higher diversity of both trees and grass species. In *Matany* nearly no signs of erosion were observed in the surveyed plots, but the diversity of perennial grasses and tree species was low compared to the other sites.

Using machine learning models trained on field and lab data collected using the LDSF and Earth Observation data (Vågen & Winowiecki, 2019; Vågen et al., 2016), we produced high-accuracy predictive maps of different biophysical indicators, including SOC and soil erosion. The maps of soil and land health indicators showed clear spatial patterns across the five rangeland landscapes.

These results demonstrate that rangeland health is multidimensional and highlight the importance of simultaneously assessing multiple indicators of soil and land health and their interactions across the plant-soil-water nexus.

Rangeland restoration in knowledge-sharing hubs

In 2021, we established four knowledge-sharing hubs, known as 'Livestock Cafés', in *Chepareria*, *Lokiriama, Matany*, and Rupa sites. Here, we engage with local communities, extension workers, NGO practitioners, and authorities to co-develop, test, and demonstrate innovative rangeland restoration and management options. We draw from the baseline assessments of soil and land health and local needs and priorities to guide and tailor restoration. Restoration interventions span a combination of agronomic, vegetative, structural, and management measures – including half-moons, retention ditches, contour bounds, manure addition, reduction of grazing intensity and 'cut-and-carry' of fodder, reseeding of indigenous rangeland grasses and forage legumes, and planting of fodder trees and shrubs. By managing the plant-soil-water-nexus, such restoration interventions contribute to halting land degradation and accelerating the recovery of degraded rangelands. Within the 'Livestock Cafés,' we have also established regenerative kitchen gardens together with local women's groups with the aim of enhancing food security and dietary diversity throughout the year and providing opportunities for income.

From the 'Livestock Cafés', the knowledge is disseminated further through a network of Community Facilitators and Lead Farmers & Pastoralists. Rangeland restoration activities across the four sites will be monitored using the newly launched Rangeland Module in The Regreening App (CIFOR-ICRAF, 2022) – a free mobile-based application for assisted citizen science data collection of restoration activities – combined with Earth Observation. These data will allow assessing the effectiveness of different restoration interventions and will provide much needed evidence regarding rangeland restoration efforts in the region. The app also provides a unique opportunity to promote wider public engagement and co-learning in rangeland restoration.

Conclusions

Restore4More will contribute to developing the capacity of restoration actors at multiple levels through context-specific co-learning and knowledge exchange. The project will provide restoration practitioners and other actors, including policymakers, local authorities, NGO's, farmers, and livestock keepers, with robust science-based evidence and tools to support and guide rangeland restoration efforts in the drylands of East Africa, improving their capacity to plan, implement, monitor, and assess restoration activities and practice adaptive management.

Acknowledgments

The LDSF surveys were conducted with financial support from Formas (Grant Nos. 2020-00478 and 2020-01557). The project 'Restore4More' is funded by Formas within the National Research Program on Climate and the National Research Program on Oceans and Water (Grant No. 2023-00307).

Assessing drought vulnerability and water resource management in the Great Artesian Basin: insights from GRACE data and climate projections under varying emission scenarios

Razeghi, M[1]; Lyons, B[2]

[1]Rural Economies Centre of Excellence, University of Southern Queensland, mahdiyeh.razeghi@unisq.edu.au; [2]Rural Economies Centre of Excellence, University of Southern Queensland, ben.lyons@unisq.edu.au

Key words: Great Artesian Basin (GAB); Climate Change Projections; Total Water Storage-Drought Severity Index (TWS-DSI); Climate Scenarios; Remote Sensing.

Abstract:
This study examines the projected impacts of climate change on drought in the Great Artesian Basin (GAB), Australia, a vital groundwater resource for agriculture, industry, and ecosystems, which is increasingly vulnerable to prolonged droughts and climate variability. Using the Gravity Recovery and Climate Experiment (GRACE) satellite data and CMIP5/CMIP6 climate model simulations, the analysis, based on scenarios RCP2.6, RCP6.0, SSP126, and SSP370, reveals increasing drought severity, particularly under high-emission scenarios. The integration of GRACE-derived Total Water Storage (TWS) anomalies with climate projections enhances drought forecasting, highlighting critical drought hotspots in southern and central GAB regions. These findings underscore the importance of adaptive water management strategies, such as managed aquifer recharge, and the role of satellite-based observations in improving water resource sustainability in the face of climate change.

Introduction
Droughts are major natural hazards, especially in semi-arid and arid regions where they severely impact water resources, agriculture, and ecosystems. Understanding drought dynamics is crucial for managing groundwater systems, such as the Great Artesian Basin (GAB) in Australia, which is vulnerable to climate change and prolonged droughts (Rohde et al., 2017; Zhao et al., 2020). Effective water resource management relies on accurate drought forecasting, which is essential for addressing long-term drought risks. Recent advancements in remote sensing, notably through the Gravity Recovery and Climate Experiment (GRACE) satellite, have greatly improved monitoring of drought conditions. GRACE's ability to observe variations in Total Water Storage (TWS) is due to its high sensitivity to changes in the Earth's gravity field, which is directly influenced by changes in water mass. This enables GRACE to detect variations in water storage across both surface and groundwater reservoirs, offering unique insights into the spatial and temporal distribution of water resources during droughts, which cannot be captured through

traditional ground-based methods such as streamflow measurements or groundwater monitoring alone (Tapley et al., 2004; Scanlon et al., 2012). GRACE data, with its global coverage and high sensitivity to changes in water storage, provides a comprehensive view of drought dynamics, particularly in regions with limited ground-based observation networks. Complementing this, climate models such as CMIP5 and CMIP6 project future temperature and precipitation patterns, offering insights into drought evolution under different scenarios (IPCC, 2014; O'Neill et al., 2016). This study leverages GRACE data to calibrate TWS estimates from CMIP5 and CMIP6 models, improving drought severity projections for the GAB across mid- and late-century periods. The integration of observational data with model projections enhances drought assessments, underscoring the importance of combining satellite data and climate models for effective water resource management in climate-sensitive regions (Scanlon et al., 2012; Zhao et al., 2020).

Case Study: The Great Artesian Basin (GAB)

The Great Artesian Basin (GAB) is one of the largest underground water reserves in the world, covering much of northeastern and central Australia. It provides vital water resources for agriculture, industry, and domestic use. The basin is crucial for Australia's water system, supporting local ecosystems and communities (Geoscience Australia, 2011). Figure 1(a) shows the GAB's geographic extent, covering Queensland, New South Wales, South Australia, and the Northern Territory, and highlighting key areas like Longreach, Broken Hill, and Birdsville. Understanding water storage dynamics in the GAB is critical, especially in the face of climate change and its impact on groundwater. Climate variability, including irregular rainfall patterns and extended dry spells, combined with rising temperatures, reduces the recharge of groundwater aquifers and increases evaporation, leading to more severe water scarcity and threatening the long-term sustainability of the GAB's water resources (Zhao et al., 2020). Satellite observations like GRACE play a key role in monitoring TWS changes in the GAB (Rodell et al., 2004). By integrating GRACE data with climate model projections from CMIP5 and CMIP6, we gain valuable insights into the basin's future water availability and drought risks under various climate scenarios (Collins et al., 2013; IPCC, 2014).

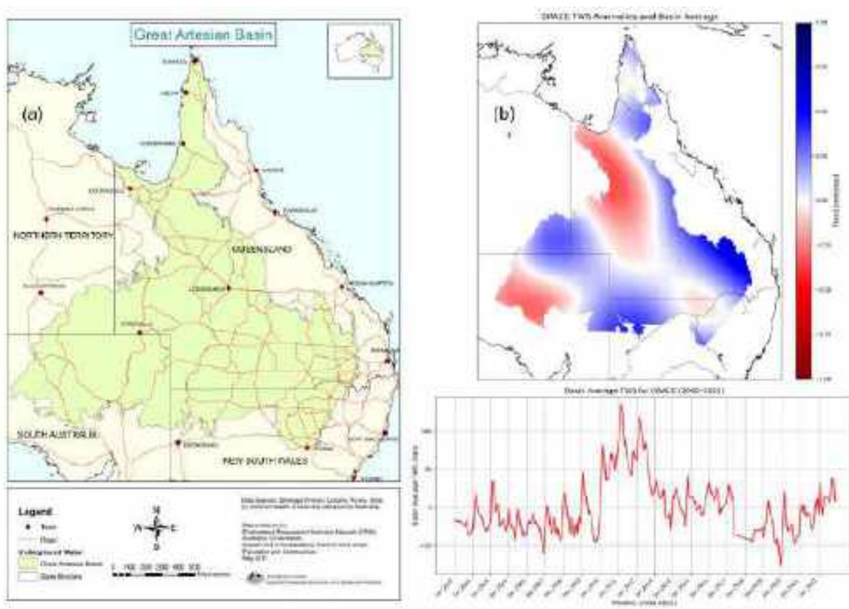

Figure 1.(a) Great Artesian Basin map, (b) Total water storage changes over GAB estimated by GRACE.

Data and Methodology

This study utilizes the Gravity Recovery and Climate Experiment (GRACE) satellite data (2002-2022) to analyse TWS anomalies in the GAB, Australia. The spatial resolution of GRACE data is approximately 250 km, providing global coverage with a focus on regional variations in water storage (Rodell et al., 2004; Tapley et al., 2004). GRACE measures changes in Earth's gravity field, providing critical insights into water storage variations over time (Rodell et al., 2004; Tapley et al., 2004). TWS anomalies are calculated by subtracting the climatological mean (2002-2022) from observed values, highlighting deviations from normal water storage conditions, which improves clarity and reduces repetition. The GRACE dataset, obtained from NASA's GRACE Data Portal, is widely used in hydrological and drought-related research. For future climate projections, we use data from CMIP5 and CMIP6 models, focusing on mid-century (2030-2059), and late-century projections (2070-2099). These models provide climate variables (e.g., precipitation and temperature) under emission scenarios: RCP2.6, RCP6.0 (CMIP5), and SSP126, SSP370 (CMIP6) (Collins et al., 2013; O'Neill et al., 2016). These scenarios were chosen because they represent a range of potential future climate outcomes, from low-emission pathways (RCP2.6, SSP126) to high-emission pathways (RCP6.0, SSP370), making them suitable for assessing the impact of various climate change scenarios on water resources and drought severity. TWS anomalies are calculated by subtracting the mean of monthly TWS values (2002-2022) from the observed values. To refine model projections, GRACE data were used to calibrate TWS seasonal cycles from CMIP5 and CMIP6 models. The calibration process involved adjusting the model outputs to better match the observed TWS anomalies from GRACE using statistical methods, such as the Root Mean Square Error (RMSE), which quantifies the difference between the model and observed values. Models with better alignment to GRACE data were weighted more heavily, based on their RMSE and structural diversity (Sanderson et al., 2017; Eyring et al., 2019). Drought severity is quantified using the Terrestrial Water Storage Drought Severity Index (TWS-DSI), which normalizes TWS anomalies by the standard deviation of monthly anomalies. The TWS-DSI indicates drought conditions based on a scale ranging from exceptionally wet to extremely dry. This method follows the World Meteorological Organization's classification guidelines, ensuring a globally consistent approach (WMO, 2012).

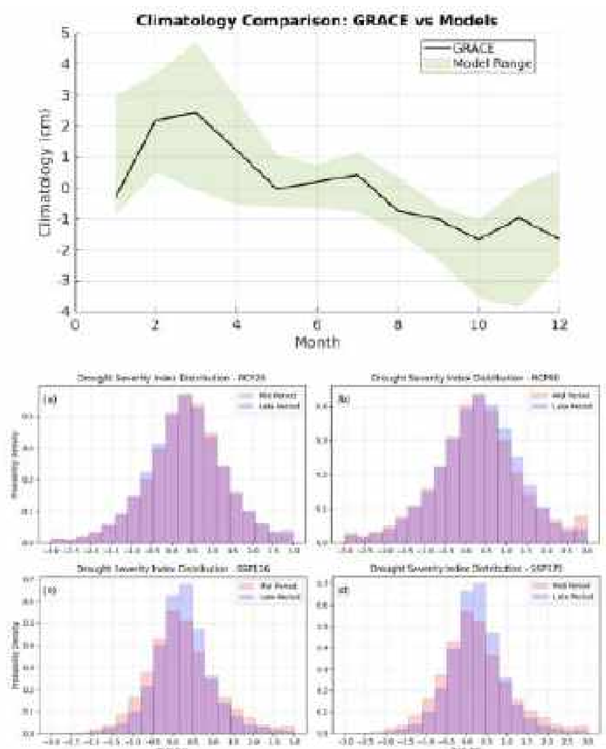

Figure 2. Top: climatology comparison between models and GRACE. Bottom: estimated drought index for mid and late century under different scenarios.

Results

GRACE TWS anomalies and basin average for the GAB (2002–2022): Figure 1(b) (top panel) shows TWS anomalies across the GAB from 2002 to 2022. Positive anomalies are observed in the northern regions, such as Weipa, while negative anomalies dominate southern areas like Coober Pedy, indicating varied water storage patterns across the basin. The lower panel of Figure 1(b) displays the basin-wide average TWS. Fluctuations include a significant positive anomaly during the La Niña event in 2010–2011 (Bureau of Meteorology, 2011), followed by a sharp decline of approximately 150% in mid-2019–2020, reflecting severe drought conditions (NSW Government Water, 2020).

Climatology comparison; GRACE vs models: The top panel of Figure 2 presents a climatological comparison between GRACE-derived TWS data and model outputs. GRACE data shows a clear seasonal cycle with higher water storage during the wet season (December to March) and lower values during the dry season (April to October). The models capture this general seasonal pattern but show discrepancies, particularly during the wet season, where some models overestimate TWS by up to 100%, likely due to overestimations in precipitation. These discrepancies highlight the need for model calibration using GRACE data to improve the accuracy of future projections.

Drought Severity Index (TWS-DSI) analysis for the GAB: The bottom panel of Figure 2 displays the probability density function (PDF) of the Drought Severity Index (TWS-DSI) for the GAB under different emission scenarios (RCP26, RCP60, SSP126, and SSP370) for both mid- and late-century periods. The PDF was derived by calculating the frequency distribution of TWS anomalies over the 2002–2022 period,

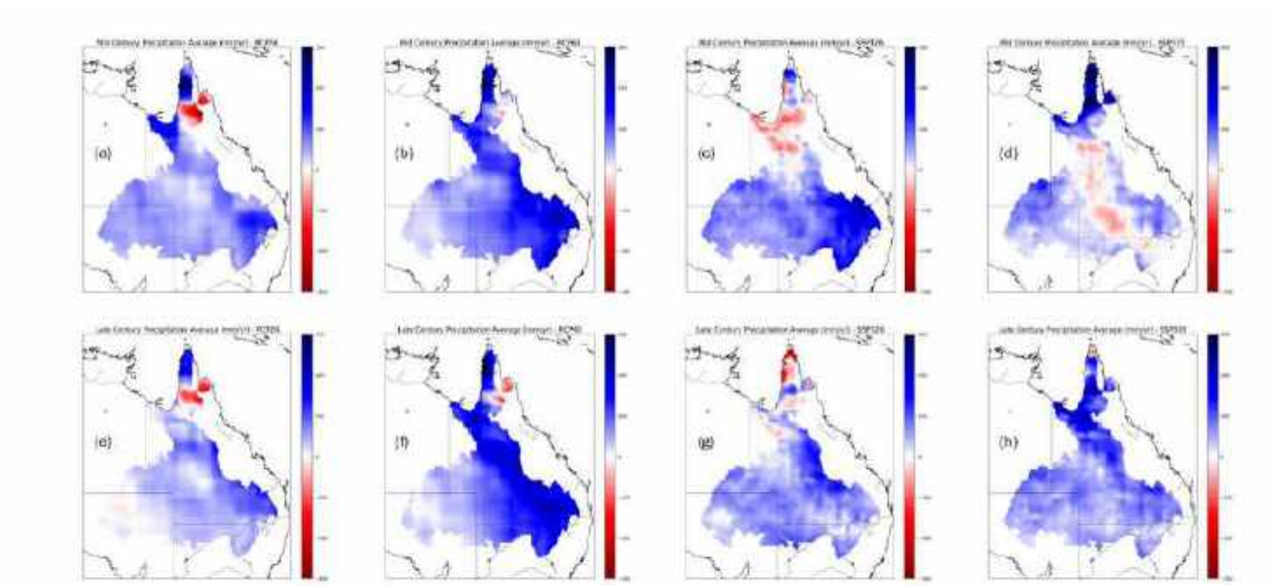

Figure 3. Precipitation projection for mid and late century under different scenarios.

categorizing the anomalies into drought severity levels ranging from -2 (extremely dry) to +2 (exceptionally wet). The histograms illustrate the distribution of drought severity under each emission scenario, with a shift toward more negative values indicating an increase in drought severity under higher emission pathways. For RCP2.6, the distribution remains relatively balanced, indicating near-normal drought conditions. However, under higher emissions scenarios like RCP6.0 and SSP370, the distribution shifts towards more negative values, signalling an increase in drought severity in the late-century period.

Climate variables and drought index correlation: Figures 3 and 4 display mid- and late-century projections of precipitation and temperature changes across the GAB, with a historical baseline (1975–2005) removed for clearer quantification of changes. Figure 3 shows a general decrease in precipitation, particularly in South Australia and Broken Hill under high-emission scenarios (SSP370), with a 20-30% reduction in some regions. These trends align with more negative DSI values observed in Figure 2. Figure 4 shows a significant temperature increase, especially in southern regions, with areas like Birdsville expected to warm by up to 4°C under SSP370, which corresponds to a 15-20% increase in temperature. This temperature increase exacerbates evapotranspiration, while precipitation deficits in southern areas further intensify drought conditions. These trends align with IPCC (2021) projections and studies by van Dijk et al. (2013) and Crosbie et al. (2010), highlighting the increased vulnerability of groundwater and ecosystems in the GAB due to climate change. The results emphasize increasing drought severity under higher emission scenarios and more moderate impacts under lower emission pathways.

Discussion and Conclusion

This study examines the projected impacts of climate change on drought conditions in the Great Artesian Basin (GAB) using GRACE satellite data and CMIP climate model simulations. The findings reveal increased drought severity across all scenarios, with the highest risks under high-emission pathways like RCP6.0 and SSP370, especially in regions like South Australia. Even low-emission scenarios (RCP2.6, SSP126) show a gradual increase in drought intensity, particularly in areas such as Broken Hill and Weipa. Temperature increases of up to 4°C, especially in southern regions like Birdsville, correspond to an approximate 15-20% increase in temperature, exacerbating evapotranspiration, which could increase by 10-15%. Precipitation deficits in southern areas, with reductions of 20-30%, further intensify drought conditions. The results emphasize that higher emission scenarios lead to more frequent and severe droughts, while lower emission pathways, such as RCP2.6 and SSP126, help mitigate extreme drought conditions. These findings are consistent with studies by Thomas et al. (2014), which suggest that higher emission scenarios are likely to result in more severe and frequent drought events. The GAB's groundwater and

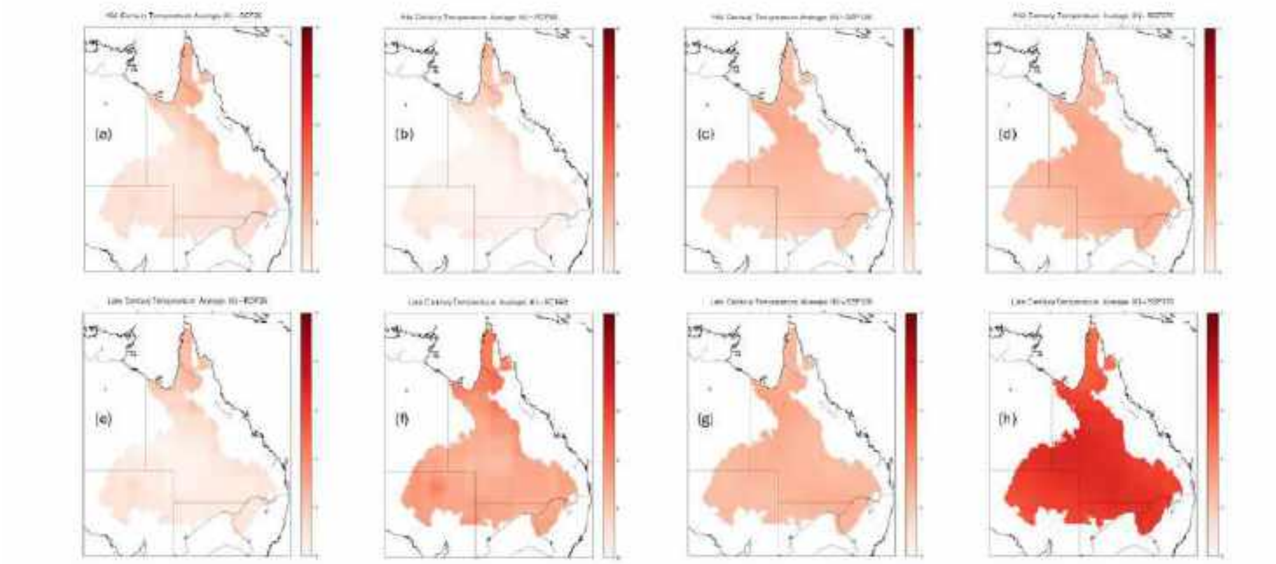

Figure 4. Temperature projection for mid and late century under different scenarios.

ecosystems are increasingly vulnerable under high-emission pathways, as confirmed by earlier studies (van Dijk et al., 2013; Crosbie et al., 2010). GRACE data has been essential for validating model projections and refining drought indices. The discrepancies between GRACE data and model outputs, such as 100% overestimation of TWS during the wet season, highlight the need for model calibration to improve accuracy in future projections. To mitigate the projected impacts, adaptive water management strategies, such as managed aquifer recharge (MAR) and improved irrigation, are crucial. Scaling up MAR in the GAB will require investments in infrastructure, alongside better real-time monitoring of groundwater levels. Transitioning to low-emission pathways (RCP2.6, SSP126) can reduce the risks of extreme droughts by approximately 10-20% and support long-term resilience in the GAB. Integrating satellite-based monitoring into decision-making will enhance drought mitigation and water resource management, ensuring sustainable water use in the region under future climate change scenarios.

Navigating technology adoption: mapping beef producers' decision journeys

Wilson, CA[1]; Hay, R[1]; McShane, C[1]; Atkinson, I[1].

[1] James Cook University, Townsville, Queensland, Australia

Key words: decision-making; customer journey map; AgTech; innovation diffusion; adoption pathways

Abstract

The adoption of agricultural technology (AgTech) and innovations by graziers is crucial for enhancing productivity and sustainability in the rangelands. However, the decision-making process is often complex and fraught with risk and uncertainty. This PhD project aims to support informed adoption decisions among beef producers in Queensland, Australia.

Participatory research interviews were conducted with a diverse range of industry stakeholders. Insights from these interviews were synthesized into a co-designed Customer Journey Map (CJM), which visually maps key decision points against the Diffusion of Innovations (DOI) stages—Knowledge, Persuasion, Decision, Implementation, and Confirmation. The CJM framework effectively guided the co-design process, enabling participants to contribute their unique perspectives.

The completed CJM provides a structured visual representation of the adoption process. It served as a pivotal tool in facilitating discussions during subsequent semi-structured interviews with beef producers and AgTech companies. By framing these interviews around the dynamic adoption process, the CJM aided in recalling crucial decision points and eliciting detailed insights into decision-making processes.

Beyond this project, the CJM serves as a versatile tool applicable to research focused on adoption decisions. Future phases will explore mapped decision points, focusing on identifying heuristics and biases that influence AgTech adoption. These insights will benefit stakeholders aiming to enhance extension and adoption programs. Additionally, findings from this study are positioned to align with current trends in artificial intelligence (AI). There is potential for personalized decision support tools to leverage this knowledge to offer tailored advice, supporting adoption and reducing decision fatigue.

Introduction

AgTech adoption is inherently complex, involving multiple stages and touchpoints, as conceptualised in Rogers' Diffusion of Innovations (DOI) (Rogers 1962). Adoption decisions are shaped by various personal, social, cultural, and economic factors, along with the specific attributes of the innovation itself (Pannell et al. 2006). Producers must weigh costs and benefits while navigating practical concerns such as compatibility with existing systems and limited technical support (Kuehne et al. 2017; Montes de Oca

Munguia et al. 2021). Additionally, the overwhelming array of available technologies contributes to choice overload, creating decision fatigue and uncertainty (Iyengar and Lepper 2000). These barriers are compounded by constrained time and expertise, which restrict producers' capacity to engage with complex technologies (Reichardt et al. 2009). Such challenges can prevent producers from effectively assessing whether a new technology offers a substantial 'relative advantage'—a key determinant of adoption, defined as a perceived improvement over current practice (Pannell et al. 2006).

Understanding decision-making within adoption pathways requires a dynamic approach that accounts for systemic and individual factors. While broader systemic barriers influence outcomes, the decision to adopt ultimately rests with producers, whose motivations and attitudes are shaped by their specific contexts (Nettle et al. 2022). Decision-making is iterative, with producers often reassessing their considerations as circumstances change and new information arises (Rogers 1962; Montes de Oca Munguia et al. 2021). Capturing these dynamics can be challenging, as participants may struggle to recall or articulate past decisions, potentially limiting insights into the complexities of the adoption process (Tversky and Kahneman 1974; Nisbett et al. 1977; Reisch and Zhao 2017; Streletskaya et al. 2020).

The 'probes approach' (Gaver et al. 1999) employs design-oriented tools for gathering data and co-exploring topics. Probes are designed to encourage participants to reflect on and share their experiences, enhance dialogue between researchers and participants, and stimulate meaningful discussion and reflection (Mattelmaki 2008). This study aims to investigate the utility of a co-designed Customer Journey Map (CJM), based on the DOI model (Rogers 1962), for exploring nuanced AgTech adoption experiences. By mapping the adoption process, the study seeks to explore how such tools might enhance our understanding of critical decision points, barriers and motivations in AgTech adoption.

Methods

This study employed qualitative methods, grounded in participatory action research principles, to explore the decision-making processes of AgTech adoption among beef producers in Queensland, Australia. The study adopted a co-design approach to ensure that outcomes were directly relevant and beneficial to the target community (Trischler et al. 2019; Rundle-Thiele et al. 2021; Moretti et al. 2022). The Customer Journey Map (CJM) framework was structured with the horizontal axis representing the stages of the DOI model (Knowledge, Persuasion, Decision, Implementation, and Confirmation) (Rogers 1962), as proposed by Ong et al. (2022). The vertical axis consists of three overarching themes (Activities, Motivations, and Barriers) to provide a comprehensive lens to capture the dynamics of the adoption journey, in a similar approach to Moretti et al. (2022). Six participants, comprising a producer, consultant, economist, station manager, social scientist, and extension officer, were purposefully selected for their extensive experience with AgTech adoption decisions, to capture a broad spectrum of perspectives and enable a deeper understanding of the adoption process and its contextual factors.

Data was collected through semi-structured interviews conducted online via Microsoft Teams. Each interview lasted approximately 60 minutes and included an introduction to the study followed by an adoption journey mapping activity. A blank CJM framework was shared on-screen, and participants' insights were recorded in real time as the interviewer guided them through each segment. Opportunities were offered for refinement. The analysis synthesized interview insights into a single map. Initially compiled as a comprehensive document, themes and connections were distilled through an iterative process. The final map was refined into a concise, single-page format designed for clarity and practicality, ensuring its effectiveness as a probe for engaging beef producers in interviews. Reflexivity was incorporated to evaluate the utility of the CJM as a facilitation tool for eliciting nuanced responses, while acknowledging the researcher's influence on the process (Finlay 2002).

Results

The co-design process proved to be a highly effective approach for developing the CJM. Conducting individual online interviews facilitated a deep and nuanced exploration of the adoption process from various stakeholder perspectives, while overcoming logistical challenges posed by a workshop format such as scheduling conflicts and geographic dispersion. This approach ensured that each participant could dedicate focused time to the mapping activity, yielding rich and varied insights critical for capturing the complexities of AgTech adoption. This co-design approach laid the foundation for a robust and adaptable CJM (Fig. 1), designed as a probe for exploring the AgTech adoption process. The CJM was piloted in a follow-up study to assess its practical application and effectiveness. Semi-structured interviews were conducted with 22 producers and AgTech stakeholders in-person, during which both participants and the researcher used the printed CJM to guide discussion.

Participants actively engaged with the CJM, which facilitated rich conversations and uncovered nuanced insights into the decision-making process that might otherwise have been overlooked. Producers frequently used the map to articulate their decision pathways and reflect on their experiences. The CJM proved effective in keeping discussions focused and re-engaging participants when thought processes stalled, ensuring interviews made the best use of limited time. In the pilot interviews, AgTech providers highlighted the CJM's value in capturing the dynamic nature of adoption, reflecting their observations of how customers often move between stages and how motivations and barriers shift in response to changing circumstances and priorities. One provider noted its utility in making the adoption process more tangible, stating, "I would like a copy of this … it would help explain things to people [in the AgTech industry] so quickly and easily.

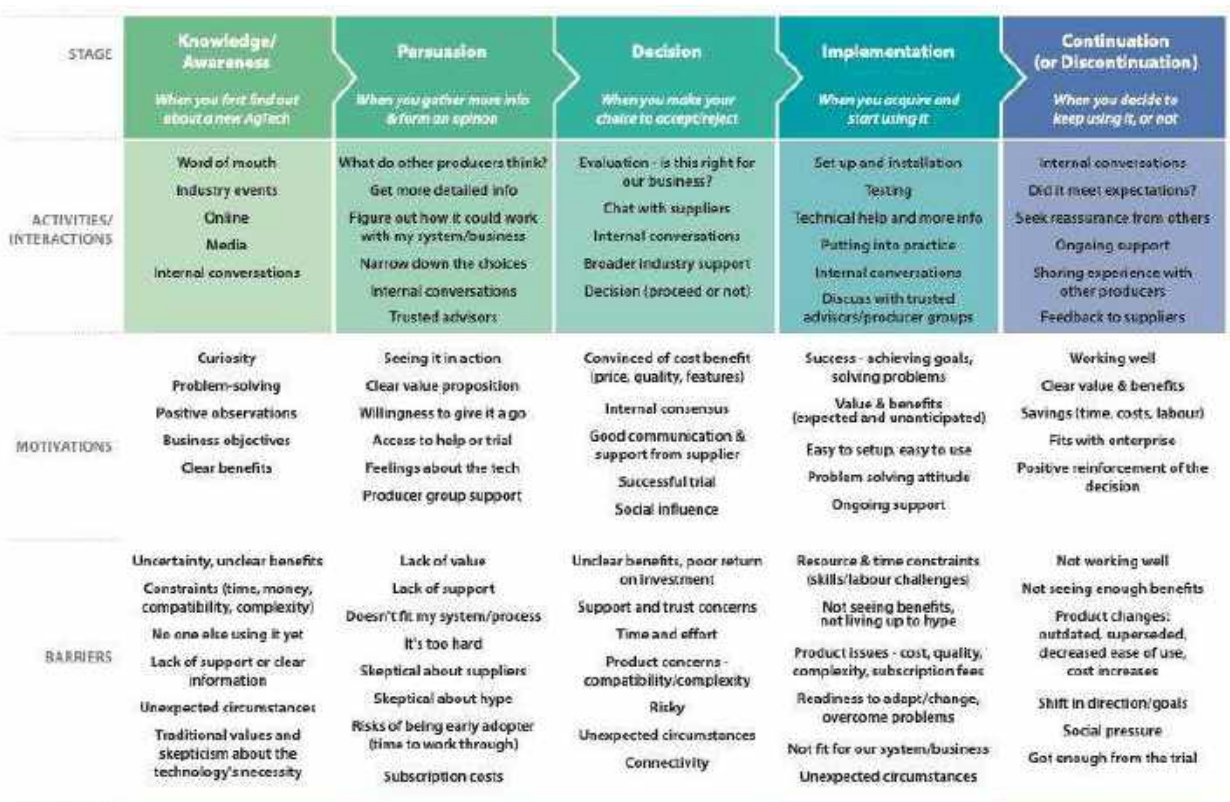

Fig. 1: Customer Journey Map (CJM) for AgTech Adoption by Beef Producers.

Discussion

Findings demonstrate the CJM as an effective probe for exploring AgTech adoption decision-making. Like other design-oriented tools described by Gaver et al. (1999) and Mattelmaki (2008), the CJM fostered participant reflection, facilitated meaningful discussions, and encouraged engagement by making abstract adoption concepts more tangible. By structuring insights across the DOI stages (Rogers 1962) and categorizing them into Activities, Motivations, and Barriers, the map aids in the examination of adoption dynamics, making it a practical tool for understanding the multifaceted challenges of adoption. Its visual and accessible format fosters participant engagement and reflection, aligning with Santos and Gonçalves (2021), who emphasize journey mapping as a method for simplifying complex processes.

Notably, the CJM serves as a valuable tool for enhancing qualitative research by structuring discussions and uncovering nuanced experiences which can be used to identify strategic leverage points for intervention. Exploring adoption pathways using the CJM aids in revealing the cascading effects of early-stage challenges. For instance, an unclear understanding of benefits during early stages often translated into a perceived lack of value and return on investment (ROI) in later stages, ultimately diminishing the perceived relative advantage.

Its adaptable design positions the CJM as a potential tool for studies across agricultural sectors and innovations (Moretti et al. 2022), holding value for stakeholders beyond academia. Developers of extension and adoption programs can harness insights to develop strategies that align with producer motivations and address barriers, enabling more targeted and effective engagement (Murray-Prior and Wright 2001; Santos and Gonçalves 2021; Nettle et al. 2022). Additionally, AgTech providers can use the CJM to better understand customer pathways and barriers and refine communication and support strategies.

The framework design and limited number of co-design contributors may have left certain aspects of adoption underexplored, such as the role of relationships and trust. However, the CJM effectively fulfilled its purpose as a facilitation tool, enabling participants in the pilot study to quickly grasp and expand upon the map, adding nuance and filling in gaps based on their own experiences. Future studies could broaden the co-design participant base, adjust the vertical axis to capture relevant factors, and experiment with more interactive probe designs to further enhance engagement and insight generation.

As a probe, the CJM provides a structured process to bridge theoretical understanding and practical application. This aligns with emerging trends in artificial intelligence, particularly the development of personalized decision-support tools. These tools could deliver tailored advice, identify leverage points, and mitigate decision fatigue to support adoption. Beyond enhancing the understanding of AgTech adoption processes, the CJM advances research methodologies and practical applications, serving as a versatile framework that can be adapted to various agricultural contexts and stakeholder needs.

Acknowledgements

Acknowledgement is given to all participants of the co-design process, whose insights were invaluable to this study. This research was made possible by an Australian Government Research Training Program Scholarship. Ethics approval was granted by the James Cook University Human Research Ethics Committee (H9412).

Enhancing rangeland management through technology: a case study of sheep and goat grazing in Montesinho Natural Park

Castro, J[1]; Fellahi, M[2]; Benmellouk, I[3]; Castro, M[4]; Yessef, M[5]

[1]Polytechnic Institute of Bragança, Bragança, Portugal; [2]Polytechnic Institute of Bragança, Portugal and Hassan II Institute of Agronomy and Veterinary Medicine, Rabat Morocco; [3]Polytechnic Institute of Bragança, Portugal and Hassan II Institute of Agronomy and Veterinary Medicine, Rabat Morocco; [4]SusTEC - Associate Laboratory for Sustainability and Technology in Mountain Regions and Polytechnic Institute of Bragança, Portugal; [5]Agronomic and Veterinary Institute Hassan II, Rabat, Morocco

Key words: Pastoralism; GNSS Tracking; Silvopastoral Systems; Mediterranean Landscapes

Abstract

The advent of advanced technologies offers unprecedented opportunities to improve the sustainability and resilience of rangeland management. This study examines the application of Global Navigation Satellite Systems (GNSS) in monitoring and optimizing the shepherding journeys of sheep and goat pastoralists throughout the rangelands of Montesinho Natural Park, Portugal.

Two distinct flocks—sheep and goats—were each equipped with a GNSS collar to monitor their routes across seasons and landscapes from April 2022 to March 2023. The study yielded 186 grazing journeys for the sheep flock and 232 for the goats. The data collected were subsequently analyzed using Geographic Information Systems (GIS) and Principal Component Analysis (PCA). These analytical methods were employed to discern patterns and correlations between grazing journeys and environmental variables, including altitude, topographic wetness, and land use types. The land use types examined encompassed orchards, oak forests, and shrublands.

The study elucidates marked discrepancies in the shepherding landscapes of the two species under investigation. The flock of sheep exhibited a distinct preference for agroforestry zones, demonstrating heightened sensitivity to climatic fluctuations, particularly during extreme temperatures. In such conditions, the sheep sought refuge in oak woods, chestnut groves, and riparian forests. Conversely, the goats demonstrated a greater utilization of rangelands and forestlands, indicative of their superior adaptability to varying environmental conditions. Additionally, seasonal variations were pronounced, with both species modifying their grazing strategies in response to the dynamic environmental changes.

GNSS data integration with GIS facilitated the visualization and analysis of grazing dynamics, offering valuable insights for developing decision support tools for pastoralists and land managers. These tools enhance the ability to make informed decisions that promote sustainable rangeland use and contribute to achieving internationally harmonized definitions. Moreover, the research underscores the potential of technology to foster collaborative rangeland research and improve the precision of monitoring and management practices.

Introduction

Pastoral systems rely on the mobility of livestock herds and the extensive use of rangelands, often adapting to some of the planet's most challenging environments. These systems are particularly significant in arid and semi-arid regions, contributing to biodiversity preservation, carbon sequestration, and the sustainable use of natural resources. Despite their importance, silvopastoral systems face increasing threats from climate change, land-use changes, and intensifying pressures on limited resources, necessitating innovative approaches to their management and sustainability (Castro et al., 2021).

The advent of advanced monitoring technologies, such as Global Navigation Satellite Systems (GNSS) and Geographic Information Systems (GIS), has revolutionized the study and management of pastoral systems. These tools enable detailed tracking of livestock movements, analysis of grazing patterns, and insights into the interactions between herds and their environments. Such innovations are particularly valuable in regions like the Mediterranean, where the intricate interplay of seasonal dynamics, topography, and land use shapes pastoral practices.

This study examines the grazing behaviour of goats and sheep in Montesinho Natural Park, focusing on how these species adapt to diverse terrains and land-use types throughout the year. By employing GNSS tracking and advanced statistical techniques, the research explores the spatial and temporal dynamics of herd movements, offering insights into the ecological roles of these species. This research contributes to the broader understanding of pastoralism in Mediterranean ecosystems, emphasizing the potential of integrating modern technologies with traditional knowledge to support sustainable rangeland management in the face of global environmental change.

Methods

This study was conducted in Montesinho Natural Park (MNP) in Portugal. The MNP features varied topography, with significant differences in altitude and climate, which influence the pastoralists' decisions, the herding process, and the animals' behaviour.

Data collection spanned March 2022 to March 2023, using advanced technologies to monitor livestock movements and environmental interactions. GNSS collars tracked daily grazing routes, recording spatial-temporal data. Environmental variables included elevation (ALT), relative slope position (RSP), topographic wetness index (TWI), and land use/land cover (LULC) categories: orchards (ORCH), oak forests (OAKF), temporary crops (TRIC), and shrublands (SHRB). Seasonal variables captured proximity to solstices (WS, SS) and equinoxes (AE, VE). Behavioral metrics included start/end times (B-6AM, E-6PM), duration (DRT), distance (LGT), and the Shannon Diversity Index (H') for grazing environment heterogeneity.

The GNSS data were exported to Geographic Information System (GIS) software for detailed analysis. The GPS collars used in this study provide a high level of accuracy, with latitude and longitude records inherently accurate to within 2 to 3 metres. Erroneous or anomalous grazing points, such as those recorded before animals left or after they entered the corral, were identified and removed to ensure the reliability of the dataset. One GNSS collar per flock was considered sufficient for accurate tracking, given the length of the grazing routes and validation from trials in previous studies.

The collars recorded data every 5 minutes, synchronized with the communications satellite, providing consistent and detailed location information. Key characteristics of grazing trips, including trip length, duration and proximity to environmental features, were calculated to provide insight into herd behaviour. Descriptive statistics were used to summarise seasonal variations in the herding process, ensuring a comprehensive understanding of the interaction between the herds and their environment.

Principal Component Analysis (PCA) was employed to assess the impact of environmental factors on grazing patterns. Simultaneously, correlation and inferential tests were utilized to identify significant relationships between grazing metrics and environmental variables. Spatial maps were created to superimpose the grazing route locations over the terrain, incorporating various land use types. A visual representation comparing seasonal grazing behaviours was developed to highlight patterns across winter, spring, summer, and autumn.

Results

GNSS locations database

A total of 16,389 GNSS location records were collected for the goat herd during the monitoring period. These records represent the goat herd's detailed movements and grazing patterns across different terrains and times. After the data cleaning process, which is essential to remove errors, inconsistencies, and irrelevant data points (such as outliers or points recorded during non-grazing activities), the dataset was reduced to 14,929 valid records, meaning 1,460 records were excluded for better accuracy and reliability of the analysis. This refined dataset ensured that only meaningful and relevant data were used to examine grazing behaviours and environmental interactions.

In the sheep herd, the dataset began with 13,510 GNSS records. After a similar data-cleaning procedure to ensure analytical integrity and precision, the dataset was reduced to 5,646 records, with 7,864 records excluded. This higher exclusion rate may reflect stricter criteria or more noise in the original data, such as points outside grazing periods or inaccuracies due to technical limitations.

Figure 1 provides a representation of the distribution of these GNSS locations over time and by date. It is critical for understanding the temporal patterns of movement and identifying any gaps or irregularities in the data collection process. By reviewing Figure 1, it can be seen that the data points were spread across the monitoring period, illustrating trends like seasonal variations or specific periods of intense activity.

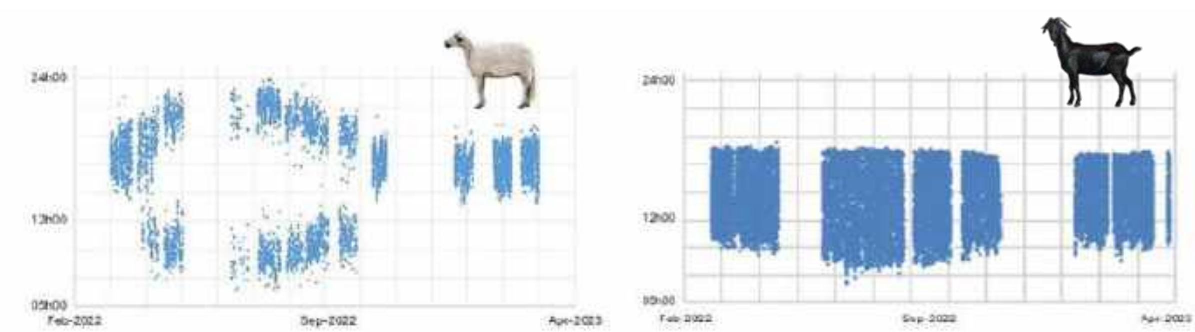

Figure 1 - Distribution of GNSS location records over time and dates for sheep and goat herds in Montesinho Natural Park.

These findings highlight the importance of data cleaning in GNSS-based studies to enhance the reliability of results and ensure that conclusions are drawn from accurate and meaningful data. The difference in the numbers before and after cleaning underscores the challenges in livestock movement tracking and the necessity of rigorous preprocessing.

The goat herd's first principal component (Dim1) is primarily influenced by physical, land use, temporal, and seasonal variables. These include the length of grazing paths (LGT), altitude (ALT), and diverse land use types like chestnut forests, oak forests, and orchards. Additionally, the Shannon Diversity Index (H') and grazing duration (DRT) contribute significantly, alongside seasonal markers such as proximity to the autumnal equinox (AE). The second principal component (Dim2) is shaped mainly by grazing duration and timing, particularly the differences in start and end times relative to 6 AM and 6 PM, which reflect temporal patterns of grazing behaviour. The third component (Dim3) highlights the influence of specific land uses like shrublands and temporary rainfed and irrigated crops. These variables are visually represented in Figure 2, where these grazing variables' spatial and temporal patterns can be observed across the goat herd's movement paths.

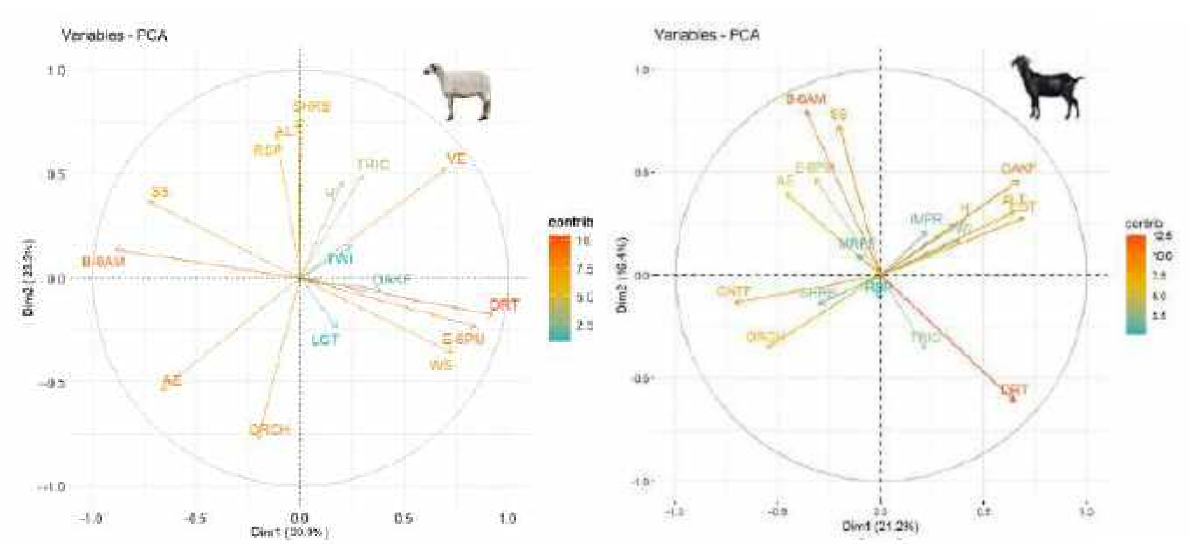

Figure 2 - Spatial and temporal patterns of grazing variables for sheep and goat herds in the Montesinho Natural Park along the first two PCA components for both herds.

In the sheep herd, the first principal component (PC1) is dominated by temporal variables, including grazing duration, the difference in grazing start times relative to 6 AM, and seasonal markers like proximity to the winter and summer solstice (WS and SS). The second principal component (PC2) emphasizes land use and topographical features such as orchards, shrublands, altitude, and relative slope position. These variables illustrate how sheep movements are influenced by terrain and land cover types. The third principal component (PC3) reflects topographical features like elevation and slope, diversity indices such as H', and seasonal proximity to the vernal equinox (VE). Figure 2 illustrates these dynamics by showing the distribution of grazing locations over different terrains and seasons, providing a comprehensive view of how these variables interact to shape grazing patterns in the sheep study.

Discussion and Conclusion

Both the goat and sheep GNSS locations reveal detailed insights into how these herds interact with their environments, highlighting differences in their behavior concerning terrain and land use throughout the year. Goats tended to explore diverse terrains, particularly for elevated areas and extended grazing paths. They relied heavily on land use types such as chestnut forests, oak forests, and shrublands, indicating their adaptability to rugged terrains and varied vegetation. This behavior was particularly evident in summer and autumn, when goats utilized high-altitude areas for longer grazing routes, reflecting their inherent ability to browse shrubs and foliage in challenging environments. In contrast, the sheep herd demonstrated more concentrated grazing patterns, favoring gentler slopes and areas with consistent vegetation. Their preference for orchards and temporary crops suggests a reliance on structured agricultural landscapes where nutrient-rich forage is readily available. Seasonal variation was marked in the sheep study, with grazing patterns closely tied to vegetation availability, particularly in spring and fall when conditions were favorable. Sheep showed reduced activity during harsher seasons, such as summer and winter, emphasizing their dependency on predictable resources and more accessible terrains than goats.

The comparative analysis highlights significant behavioral differences, as previously reported by several authors (e.g. Castro, 2004; Castro and Fernández-Núñez, 2016). Goats displayed greater adaptability to rugged terrains, utilizing steeper slopes and higher elevations, consistent with their physiological traits and foraging behavior. They were also more versatile in their land use, exploiting a broader range of vegetation types, including shrublands and forested areas. On the other hand, sheep concentrated their grazing in more controlled and accessible areas, thriving in environments with dense vegetation and less topographical challenge.

Both herds exhibited seasonal variations in grazing behavior; however, sheep were more directly influenced by climatic conditions and vegetation cycles, whereas goats maintained consistent foraging patterns across seasons. This adaptability of goats makes them particularly suited for managing vegetation in rugged and heterogeneous terrains, whereas sheep are better suited to structured landscapes like agricultural zones.

In conclusion, the results emphasize the ecological roles of each species in pastoral systems. Goats effectively manage vegetation in challenging and underutilized terrains, while sheep excel in agricultural settings where forage is predictable and abundant. These findings provide valuable insights for sustainable land management and adaptive strategies to address changing environmental conditions, ensuring the resilience and productivity of pastoral practices.

Key words: stocking rate; remote sensing; decision support tool; rangeland production; grazing

Abstract

Grasslands, shrublands, and savanna ecosystems worldwide are often grazed by domestic livestock. These vegetation types are critical for human flourishing and are vulnerable to overuse and degradation when local socio-economic conditions or misunderstanding of plant ecology leads to overuse. On large grazing areas, whether used as private property or as common pool resources, the ability of plant communities to retain rangeland health attributes of soil stability, hydrologic function, and biotic integrity depend on both stocking rate and careful application of patterns of grazing timing, duration, severity, and frequency. Sustainable stocking rates depend on judicious allocation of available forage. Historical stocking rate tools have assumed that land managers have accurate information on forage quantity and that a static sustainable stocking rate can be developed. But in non-static arid and semi-arid ecosystems already defined by resource scarcity and prone to threshold events driven by abiotic variables, the inherent interannual variability of precipitation and unpredictable net primary herbaceous production pose particular challenges for pastoralists. Washington State University Extension, in partnership with the University of Arizona and the United States Forest Service, developed a free grazing decision support tool that incorporates historical forage production and variability with user-defined animal behavior parameters and spatial distribution to estimate livestock terrain use. We show how StockSmart allows stocking calculations and grazing planning based on spatially-explicit estimates of available forage rather than total forage. It also allows testing infrastructure investments against resulting increases in forage availability. These considerations are critical for avoiding ecological state changes through overgrazing into degraded but stable conditions.

Introduction

Ranchers and public land managers collectively make land use decisions on over 700 million acres of rangelands in North America (Havstad et al., 2007). These lands provide a broad array of ecosystem services critical to human flourishing. In addition to food, fiber, and habitat (SRM 2022), humans have connection to land that is hugely influential on physical health, mental health, and social cohesion (Dean et al., 2021). Maintaining the ecological integrity of the nation’s rangelands is extremely important and the management actions influencing ecosystem processes and attributes are made predominantly by ranchers and public land managers. Grazing is a significant and visible management factor influencing plant community trajectories, wildfire mitigation, wildlife habitat, water relations at the plant-soil interface, pollinators, and more. The most basic grazing decision is "how many animals can be grazed for how long?" Although numerous factors contribute to the effects of grazing over time, the decision of stocking rate is unavoidable; literature syntheses indicate it is critical to rangeland health, independent of intensity of animal distribution (Bestelmeyer & Briske, 2012; Briske et al., 2008; Provenza et al., 2013).

More broadly, rural communities depend on the financial viability and resiliency of pastoralists and related businesses. Agricultural businesses, especially rangeland-based livestock production, depend on protecting the productive capacity of the land and sustaining ecosystem functions. Profitable businesses enable family stability and farmer mental wellness at the individual scale and social resiliency at the community scale, contributing to quality of life. The nearly inevitable result of ranch failure is fragmentation and environmental degradation of various kinds. The less common trajectory of land purchase and passive management can be ecologically dysfunctional as well. There is tremendous need to enable economically sustainable grazing use of private and public lands, and StockSmart can contribute to ensuring that good data underlie key sustainable stocking decisions. Federal, state, and tribal land managers make decisions about grazing on extensive, heterogenous rangelands, and these decisions are sometimes controversial. Ranchers make decisions on private lands and contribute to decisions and plan execution on private and public lands. All of these decisions directly impact rangeland resources. Stocking rate is a primary management variable in grazed rangelands. Poor grazing management, which includes excessive stocking rates, can have cascading negative environmental effects. Climate smart grazing management, which begins with an adaptive stocking rate, can maintain and improve various ecosystem services and values through promoting biodiversity, heterogeneity of plant community types and seral stages, limiting wildfire risk, and enhancing wildlife habitat attributes. Improved management may depend on investment in grazing infrastructure, practices that must be effective in order to justify the cost. StockSmart allows users to quantify the increases in accessible forage production due to proposed infrastructure development, including watering sites, virtual fencing boundaries, or physical cross-fence to better control timing of grazing.

Methods

StockSmart, a web application developed by the authors and University of Arizona Communications & Cybertechnologies, allows users to access accurate, spatially-explicit forage production data and combine it with spatially-explicit predictive terrain use by livestock to develop reasonable starting stocking rates that are responsive to interannual variation in herbaceous above-ground biomass and are based on calculations of forage in the areas actually accessed by grazing animals (Hudson et al., 2021). StockSmart addresses key challenges in landowners' and managers' abilities to accurately estimate grazing capacity on rangelands under their control, to track and monitor changes in the vegetation under a particular set of management decisions, and to prepare for and adjust their management as forage availability changes with climate change. Development of StockSmart had three sequential elements: 1) Develop a spatially-explicit, web-based decision support tool (DST) that accesses Normalized Difference Vegetation Index (NDVI)-based rangeland forage production data for an area of interest, allows the user to define key factors that determine rangeland accessibility, and produces maps of stocking rate and other synthetic metrics showing variation through the growing season and from year to year. 2) Convene an advisory group of rangeland owners and managers to provide actionable input and real-life pilot cases to test the tool on, ensuring that the DST provides relevant and actionable information needed for improved grazing management decisions. 3) Engage with Extension agents and specialists, public land managers, and other rangeland advisors through existing communication networks to build awareness, collect valuable feedback, and encourage early adopters to use the DST. The access to data characterizing variations in forage availability and other key factors will improve private landowners' and public land managers' ability to enhance the sustainability of the nation's forests and rangelands, provide ecosystem services and market goods, improve ecological and operational resilience to climate change, and support rural livelihoods.

Results

Forage production data

Advances in remotely-sensed data and enhanced access to these data by ranchers and public land managers offer opportunities for improved calculations of stocking rates across vast rangeland environments. The primary data that StockSmart uses emanate from the Rangeland Production Monitoring Service (RPMS) (Reeves et al., 2021) and the Rangeland Analysis Platform (Allred et al., 2021). Based on the RPMS data, StockSmart computes the historical mean and standard deviation of total annual production from 1984 to 2024, giving one value for each 30x30m square (less than a quarter of an acre, approximately one tenth of a hectare). It then uses the most recent Vegetation Cover data from the Rangeland Analysis Platform (RAP) to apportion total production into shrubs, herbs (annual and perennial), and tree growth.

Users identify an area of interest, including multiple pastures, enter on the map where water sources are (point, polyline, or polygon), select a harvest coefficient (how much of ANPP one wishes to allocate to grazing consumption), and calculate available forage based on the historical mean 1984-2024 and one standard deviation above and below the mean.

Accessibility of forage

To determine what forage is actually accessible to the animals grazing these rangelands, StockSmart corrects the forage production values based on tree canopy cover, terrain, and distance to water. Where remotely sensed estimates of understory forage are unreliable because of the interference of tree canopies, some basic linear models are used to estimate forage growing beneath the trees. All the edible forage is then corrected, accounting for how steep a slope your livestock will traverse, and how far from water they will disperse. After also adjusting the accessible forage using a harvest coefficient—the fraction of total forage produced that is assigned to grazing animals for consumption—and a shrub utilization fraction (some animals browse shrubs, some don't), StockSmart provides the user with a final number. This can be either the number of days your herd of cattle could graze, or the number of head of cattle that could graze there for a predefined length of time.

Decisions StockSmart can inform

With access to accurate, spatially explicit historical forage production data, ranchers and other rangeland managers can fine tune grazing management decisions and compare scenarios (and save them, if one creates an account). One can visualize what areas are too far away from water to be accessed by livestock and explore how stocking rate changes by adding a source of water in that part of a pasture. One can explore whether dividing pastures as well as developing water would make a big enough difference in terms of available forage to be worth the investment in fencing. The historical variations in forage production—and therefore stocking rate—are particularly valuable as the climate continues to change. StockSmart will not indicate when, how, and how much to graze, but it will provide robust estimates of how much forage is available with realistic parameters on where animals will graze and will provide clarity on how variable that forage is likely to be from year to year. When paired with careful grazing planning and monitoring of rangeland health, it provides a very useful additional tool in the rangeland manager's toolbox, to help understand and deal with the complexities of maintaining healthy herds and healthy rangelands, now and under a changing climate.

Discussion

StockSmart is available now at Stock-Smart.com; the geographic range is currently limited to the 11 Western U.S. states, but efforts are underway to expand StockSmart to the rest of the U.S. and a few other countries, including Australia. It is currently being used by federal, state, and tribal entities to plan grazing on large landscapes. It has been used in throughout the Western US in public land management scenarios. Uses have included quantifying appropriate stocking rates from Arizona to Canada and for evaluating the value of grazing lands for the purposes of land purchases. The main uses thus far have been for evaluating federal allotment management plans as well as providing a "second opinion" to evaluate field observations obtained by consultants and managers alike. In addition, it offers a unique platform for teaching range management concepts to various age and user groups.

Key words: weather and climate; forecasting; region; biomass; rangeland

Abstract

Forecasting climate and plant production provides an advantageous way to move from reactive to proactive grazing land management. Throughout grazing lands water availability and temperature are primary drivers of annual net primary plant production (ANPP) and total annual precipitation is a fundamental indicator of ANPP in native plant dominated communities that receive less than 500 mm of precipitation. In this paper we review the process by which forecasts are produced and showcase several examples of where climate and plant production forecasts can be useful in diverse US rangeland ecoregions. While forecasting is probabilistic and may not be beneficial in all circumstances, our results suggest that if forecasts are used over time, they can provide higher quality information than just chance alone. Collectively, climate and plant production forecasting could aid in moving grazing land management from a reactive to a proactive discipline by allowing producers to prepare for drought or flooding events, set appropriate stocking rates and avoid inflated hay costs, select the most appropriate crop species for annual conditions, and improve rangeland success by only seeding when weather conditions are suitable for establishment.

Introduction

Water availability and temperature are primary drivers of annual net primary plant production (ANPP) across rangelands (Bradford et al. 2006; Swain et al. 2016). Rangeland plant production is particularly affected by these factors as total annual precipitation is a fundamental indicator of ANPP in native plant dominated communities that receive less than 500 mm of precipitation (Huxman et al. 2004; Hsu et al. 2012; Williams et al. 2023). While climate can be used to produce reliable rangeland plant production forecasts, spatiotemporal climate forecasts first need to be tested for accuracy against historical weather data to ensure quality model output.

Historical climate data

Historical climate data can be acquired in various formats. The highest quality historical climate data are from stationary weather stations (Stawowy et al. 2021; Daly et al. 2008). Weather stations are, however, expensive to acquire and maintain. Across rural grazing land regions, few and sparsely dispersed meteorological tracking has limited quality spatiotemporal climate data to widely distributed point-scale locations (Hardegree et al. 2018). To overcome this limitation, scientists have used gauge data, remote-sensing inputs, and both data interpolation and disaggregation schemes to produce daily historical climate estimates of precipitation, temperature, relative and specific humidity, dew point, radiation and wind velocity, as well as derived estimates of reference evapotranspiration data at 1-4 km gridded spatial resolutions across the contiguous US (Daly et al. 2008; Thornton et al. 2014; Mourtzinis et al. 2017). These gridded databases include PRISM (Daly et al. 2008), DayMET (Thornton et al. 2014), GridMET (Abatzoglou 2013) and others (Mourtzinis et al. 2017). Gridded climate databases like these provide historical data continuity from 1979 until present and can be used across extensive or multi-site field studies where the deployment of weather stations is impractical (Hardegree et al. 2018). While these data have helped overcome data limitations across space, they are still imperfect. The process of statistical data downscaling, for example, can result in significant modelling uncertainty, as averaged and interpolated values cannot reflect complex spatial and temporal variations in climate variables at sub-daily scales. This limitation particularly applies to soil erosion applications that require fine-scale estimates of precipitation timing and intensity (Fullhart et al. 2024).

Stochastic weather generators are another modelling tool that can be used to simulate probabilistic estimates of daily weather time-series that capture additional features of daily and sub-daily climate dynamics (i.e., daily means, variances and covariances, frequencies, extremes, etc.) (Wilks and Wilby 1999). While initially used in association with individual weather stations to simulate probabilistic estimates of historical weather data, Fullhart and his colleagues have expanded the utility of one of these models, i.e., the CLIGEN climate GENerator, for estimating weather time-series across large spatial regions, from hourly to annual temporal scales (Fullhart et al. 2023; Fullhart 2023; Fullhart et al. 2022; Fullhart et al. 2021). Given the spatial and temporal availability of historical weather data and probabilistic scenarios from stochastic weather generators, reliable climate and plant production forecasts, and probabilistic plant-production scenarios can be developed.

Forecasting application and process

Seasonal climate forecasts are being used in a growing number of agricultural and natural resource modeling applications (Mo and Lettenmaier 2014; Klemm and McPherson 2017). These applications have been facilitated by the availability of seasonal forecasts of monthly temperature and precipitation from the North American Multi-Model Ensemble (NMME) program (Kirtman et al. 2014; Becker et al. 2014; Schantz et al. 2024; Roy et al. 2020). To test forecast skill (or reliability as measured via a P-value of $P<0.10$), hindcasts (or retrospective forecasts) are regressed against historical climate data. For this process, hindcasts from models used in the NMME program are acquired, as described by Kirtman et al. (2014) and matched to the spatial resolution of historical climate data at the appropriate grid scale, following a Bias Correction-Spatial Downscaling (BCSD) procedure such as in Barbero et al. (2017). For the studies we showcase here forecast model output from NMME was downscaled to match the 4-km resolution of historical gridMET weather estimates.

Climate forecast skill

In our first study, we evaluated the quality of point-scale forecasts across four US rangeland ecoregions (Fig. 1; Schantz et al. 2024). Key take aways from this study were that 1) forecast skill varies by region with the highest forecast skill in the Desert Southwest and relatively poor forecast skill in the Southern Great Plains; 2) temperature forecasts were found to have higher relative skill than precipitation forecasts; 3) we found no differences in forecast skill as a function of the forecast lead time but forecast skill varied strongly with the season for which the forecast was made; and 4) multi-model aggregate forecasts often had synergistic skill when compared to both individual model forecasts and forecasts based on the ensemble mean of all available models (Schantz et al. 2024).

Plant production forecast skill

Additional region-specific studies have shown that climate forecasts could be used as input into plant-production models to produce reliable estimates of forage yields (Fig. 2,3; (Schantz et al. *In Press-b;* Schantz et al. 2023a). In the California Annual Grassland, for example, forecasts reliably estimated plant production across most of the growing season at two sites and in three of the seven forecasting months at an additional study site (Schantz et al. 2023a). Forecast skill was shown to vary seasonally (Fig. 2) with the best forecasts produced in February following winter precipitation inputs (which is the dominant precipitation time in these regions) and when annual grasses are just beginning growth (Schantz et al. 2023b; Schantz et al. 2023a). This finding has practical application for livestock production systems as most cow-calf operations make stocking decisions in winter (January and February) and having an estimate of potential plant production would aid in the ability to justify alternative stocking decisions. Similarly, in the Great Basin we found that skillful plant-production forecasts were possible, but that forecast skill varied by inherent site conditions, such as, aspect, slope and dominant plant community (Fig. 3: Schantz et al. *In Press a,b*).

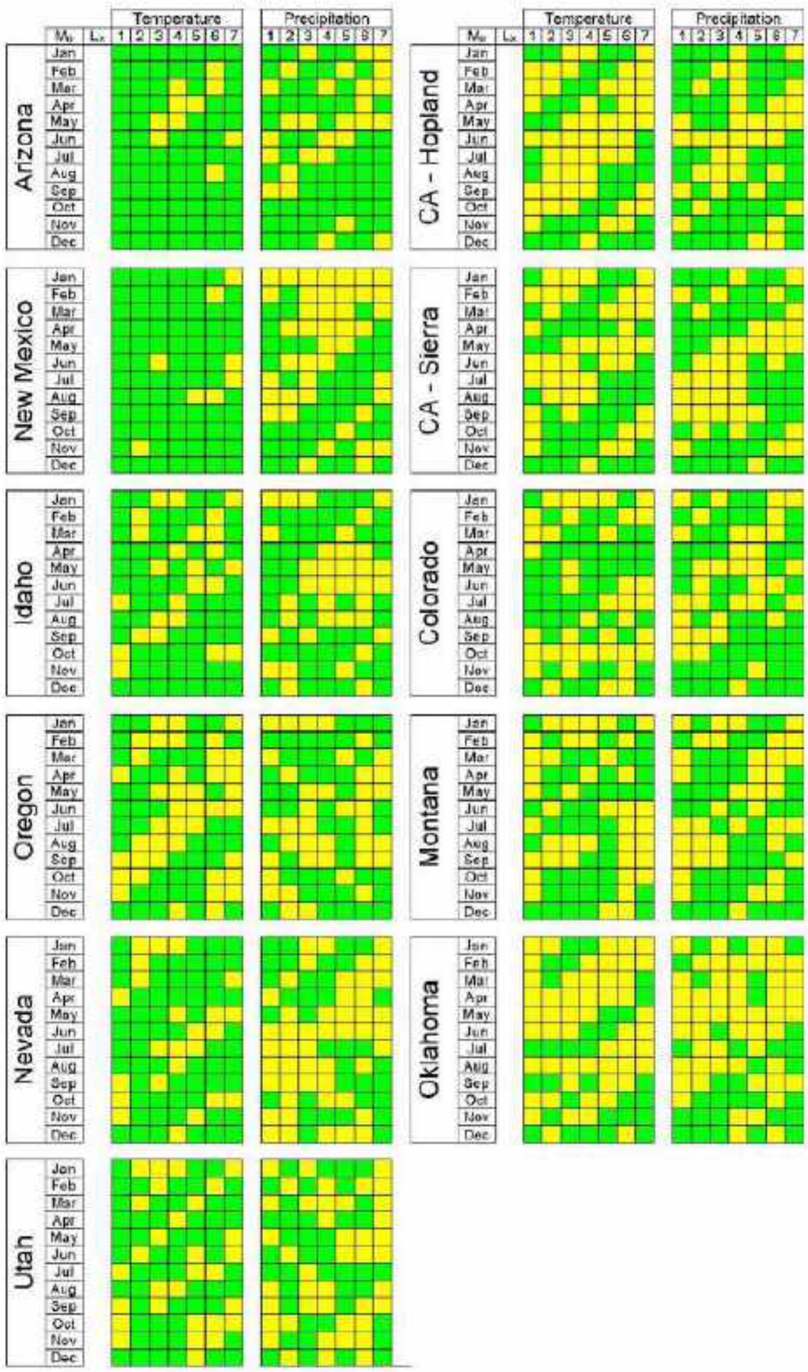

Figure 1. Skill map of 84 temporal scenarios for estimating monthly mean temperature and total precipitation at each point scale rangeland site as a function of the month in which the forecast was made M_0: Jan-Dec) and the forecast lead time L_x 1-7 months. This figure is from Schantz et al. 2024a.

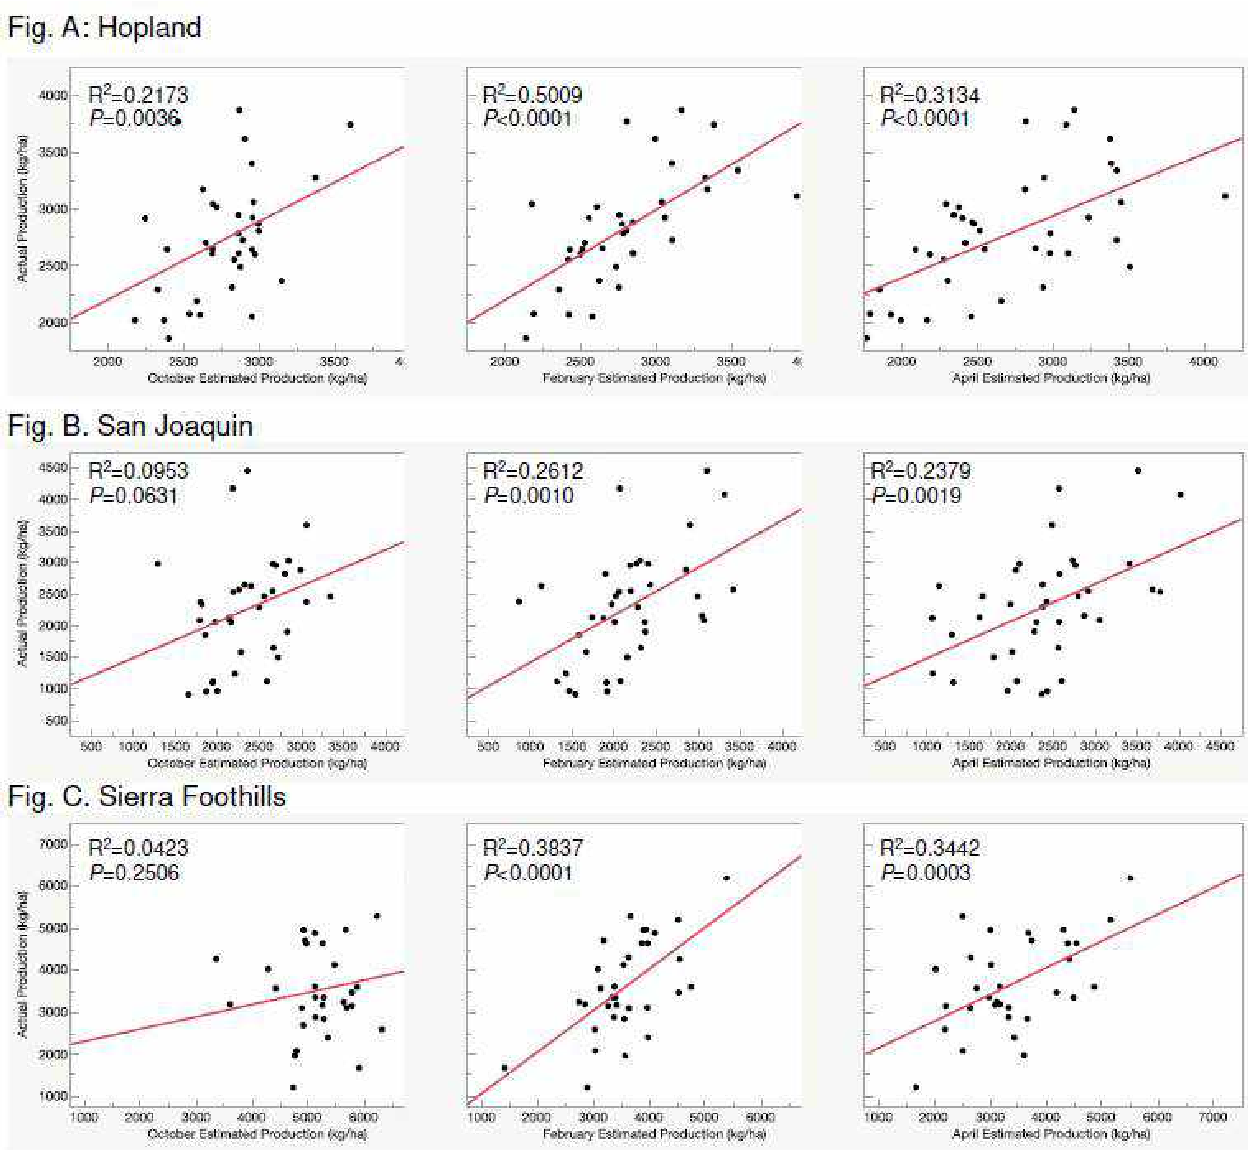

Figure 2. Regressions of actual to forecasted plant production across the study years 1982-2022 for the months of October, February, and April at three California Annual Grassland study sites. Fig. A refers to the Hopland site, B to the San Joaquin site, and C to the Sierra Foothills. This figure is from Schantz et al. 2023b.

The Future of Forecasting

Currently our team is working to provide better forecasting data access and improved tools for using forecasts in diverse agricultural and natural resource modeling applications. Upcoming projects include additional regional assessments of seasonal forecasting skill and evaluations of the utility of climate data type (i.e., stationary weather station, gridded and model-generated climate scenarios) across land use application and ecoregions associated with the Long-Term Agroecosystem Research (LTAR) network.

Conclusions and Implications

Forecasting provides an advantageous way to move from reactive to proactive management. Proactive management would allow producers to better prepare for drought or flooding events, set appropriate stocking rates and avoid inflated hay costs, select the most appropriate crop species for anticipated seasonal conditions, and provide recommendations for rangeland seeding. The process of forecasting begins by accessing high quality climate data. While stationary weather stations provide the highest quality data, they are limited to point-scale locations. Gridded and hybrid gridded stochastic weather generators can help overcome this limitation by providing quality weather information across space. Even with the best historical climate data inputs, forecasting skill will be dependent upon the interaction between region and time of the year. Similarly, the skill of plant production forecasts will depend on the interactions of area of interest, time of year, and plant species phenology. While forecast utility is probabilistic and may not be beneficial in all circumstances, our results suggest that consistent use of climate forecasts could improve the efficiency of agricultural management practices.

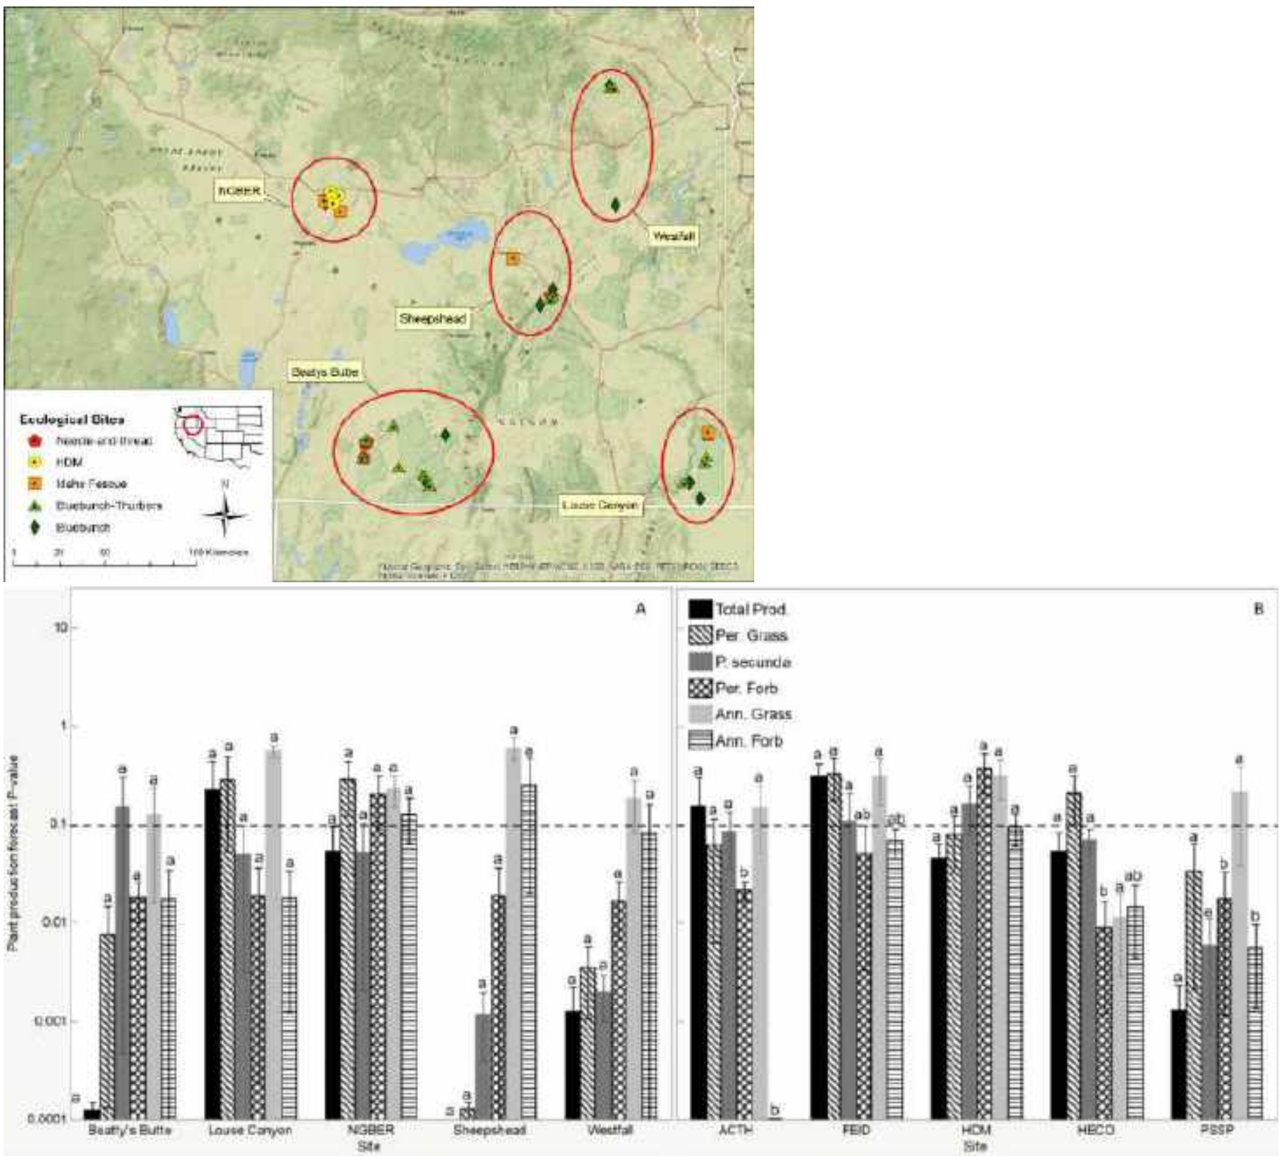

Figure 3. Upper figure refers to the geographical sites and the associated ecological states within those sites.

Lower figure refers to the skill as measured via a *P*-value ($P<0.10$) of forecasts. Figures are from Schantz et al. *In Press*.

Key words: Pasture Biomass; Remote Sensing; Data Analytics; Sustainability; Decision-making

Abstract

The Australian Feedbase Monitor (AFM) is a new grazing management tool that gives Australian land managers satellite insights into their feed capabilities. It is an online portal codeveloped between CiboLabs and Meat and Livestock Australia (MLA) to improve the understanding and management of Australia's pasture and fodder feed base. The portal is free to MLA members and supported through a broad-based extension program. We used over 5000 site-based total standing dry matter (TSDM) measurements from pasture cuts, rising plate meter transects and expert observation to build a satellite-based TSDM estimate with similar accuracy to the field observations.

This model produces national TSDM estimates every five days based on the previous 30 days of imagery. The coincident application of a fractional cover model allows the TSDM estimates to be partitioned into green and dry components, allowing additional applications such as pasture quality estimation, bushfire risk assessment and ground cover analysis. Based on the European space agency Sentinel-2 satellite, these products are available back to 2017. This enables producers to understand the trends in their farms' pasture production, including rainfall, ground cover, and biomass, to place this season in the context of previous years.

As part of this tool, training and extension programs have been developed to support producers using the data for feed budgeting and to improve planning to respond to seasonal changes. This data is also used to identify underperforming areas of the farm or areas that may benefit from management changes. Further enhancements are planned to support a greater range of visualisations, farm metrics, and comparisons, which will drive adoption and help producers understand this tool's benefits and limitations.

Introduction

The Australian red meat industry needs help meeting market demands due to fluctuating livestock availability, influenced by variable pasture resources. This variability stems from rainfall, grazing pressure, and land conditions. Innovative technologies are being developed to enhance feedbase and animal management for improved productivity and sustainability.

In partnership with Meat and Livestock Australia (MLA), Cibo Labs has developed the Australian Feedbase Monitor (AFM). This groundbreaking grazing management tool leverages satellite imagery to give land managers valuable insights into their feed capabilities. This online portal aims to enhance the understanding and management of Australia's pasture and fodder resources, ultimately supporting a more profitable and sustainable red meat industry.

Methods

The development of the Australian Feedbase Monitor (AFM) followed a comprehensive process to ensure its effectiveness and applicability.

Data Collection and Preprocessing:

We collected and curated 5,100 Total Standing Dry Matter (TSDM) measurements from diverse locations across Australia, including sites collected by Cibo Labs, clients and collaborators. These field data were guided by a dedicated field data collection app that assists the user in collecting field data along a 50m transect, suitable for calibrating Sentinel-2 10m spatial resolution imagery and aimed to capture variability within and between species, growth stages and land types in the grazing regions, ensuring the model's robustness. Measurements were obtained through multiple techniques, including pasture cuts (31%), rising plate meter transects (9%), and expert observations (60%), allowing for a broad analysis of measurement types and variability. We acquired the five closest cloud-free Sentinel-2 satellite images for each site, giving us an effective window of 20 days around the field date. Coincident photography and GPS locations enable Rigorous quality control to be applied to the field and satellite data to remove outliers and address inconsistencies, such as cloud contamination and location error.

Model Development:

We used a five-hidden-layer, multilayer perceptron regression model for TSDM prediction, known for its capacity to learn complex relationships between input (satellite features) and output (TSDM) variables. The dataset was split into 50% training and 50% validation subsets to prevent overfitting and ensure generalizability. We optimised parameters using the Adam optimiser coupled with 50% layer dropouts, a layer norm constraint of 1.0 and a robust Huber loss function to enhance accuracy and prevent over-prediction. The model's performance was evaluated using metrics such as Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE).

Model Validation and Refinement:

A 10-fold cross-validation method ensured robust validation, dividing the data into subsets to iteratively train and test the model. We generated 16 initial realisations of the model to assess hallucinations and used an adversarial method to select the four best candidate models for additional expert evaluation. We adopted a "living model" approach, using an ML Ops framework to continuously update the model with new field data to maintain accuracy and relevance as conditions evolve.

Extension and Training:

The extension program of Cibo Labs commenced in March 2022, with activities increasing following the formal launch of the Australian Feedbase Monitor in November 2022. As of December 2024, the Cibo Labs extension team had facilitated 236 engagement events, connecting with 16,700 producers and 3,486 consultants through various platforms like field days, conferences, and webinars to boost pasture assessment and grazing management awareness. These figures reflect program activities conducted over a 33-month period from March 2022 to December 2024. The team was crucial in industry initiatives such as NT TRM Rain Ready Rangelands and MLA EDGE Grazing Fundamentals. They also developed the

'Grazing for Growth' workshop to enhance producers' confidence using pasture assessment and forage budgeting tools.

Results

Table 1 shows the cross-validated satellite TSDM error metrics for various ranges of TSDM values. Figure 1 shows the cross-validated results and associated confidence envelopes for the field data and the predictions. The median absolute percentage error of less than 30% over most of the model's range aligns closely with field measurement error and demonstrates its reliability in offering critical data to producers. There is still a significant error in the 0 to 1000kg/ha range, which reflects the variability of field estimates and difficulties associated with some soil colours when the estimation area is predominantly bare ground. Additional field sites are being collected to better sample these environments and update the model in early 2025. The model is used to supply rolling monthly pasture biomass estimates that are updated every five days. This enables producers to make informed decisions regarding grazing management, stock movements, and supplementary feeding, optimising their operations.

Table 1 - Cross-validation metrics for selected TSDM ranges.

TSDM range	Mean Error (kg/ha)	StDev (kg/ha)	RMSE (kg/ha)	MAE (kg/ha)	MAPE (%)
0 - 1000	287	543	618	184	90.5
1000 - 2000	35	563	564	235	25.7
2000 - 3000	268	735	783	453	24.0
3000 - 4000	618	892	1085	637	24.3
4000 - 6000	1218	1193	1705	1073	27.9
6000 - 10000	2404	1915	3074	2263	35.1

Producers who have participated in extension activities were surveyed before and after the event, focusing on their confidence in developing forage budgets. Participants, particularly those attending Grazing for Growth, showed significant increases in their understanding and confidence in forage budgeting, specifically in accessing and applying data provided by the AFM or PastureKey.

Additionally, the AFM enriches producers' understanding of pasture trends by providing historical data since 2017. This allows for a comprehensive analysis of factors such as rainfall, ground cover, and biomass, helping producers make informed decisions for the current season while also planning for the future. The tool's broad industry adoption reflects its perceived value, with over 4,400 registered users managing more than 52 million hectares as of December 2024.

Furthermore, extension activities have equipped producers with practical tools and knowledge to integrate this data effectively into their strategies, leading to a measurable 58% increase in confidence in forage budgeting. This increase is benchmarked against pre-event survey responses, where participants rated their confidence in key areas such as estimating available feed, calculating livestock demand, and making stocking decisions based on AFM or PastureKey data. Post-event surveys substantially improved participants' ability to apply these skills independently. These efforts have heightened awareness and enabled actionable improvements in grazing management practices, enhancing efficiency, resource utilisation, and resilience against climate variability across diverse production systems

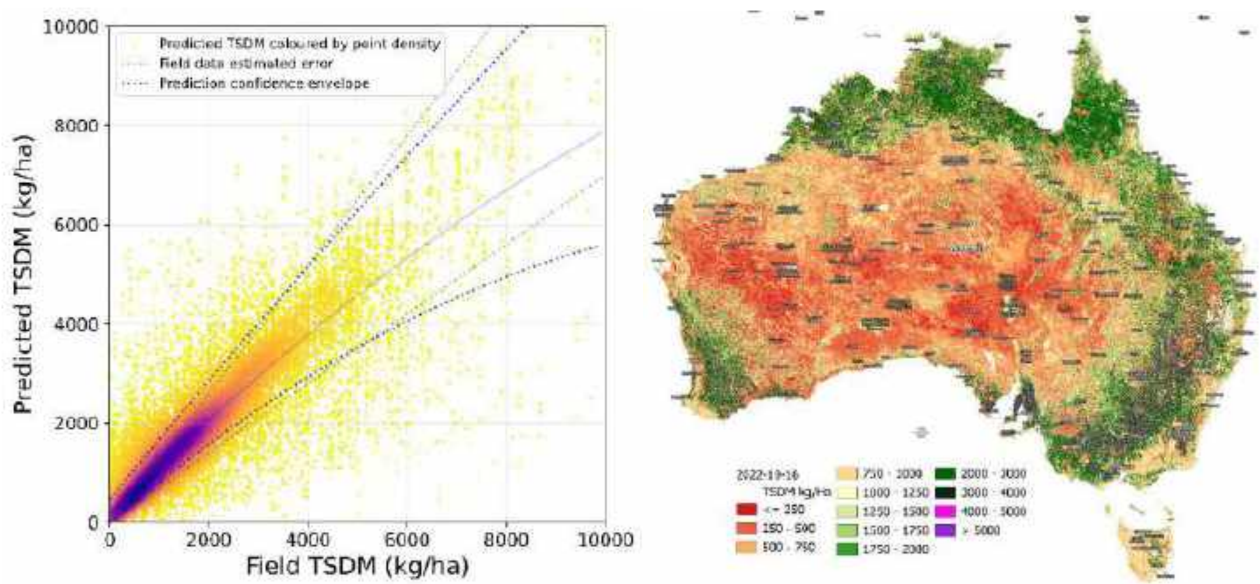

Figure 1 - Australian feed base monitor predictions vs field-based estimates (left) and example model output for 16 October 2022 (right).

Implications

The Australian Feedbase Monitor represents a significant step forward in grazing management. It gives producers powerful data-driven insights to optimise their operations and contribute to a more sustainable and profitable red meat industry. Continued research, development, and ongoing producer engagement will further enhance the AFM's capabilities and accuracy and ensure its long-term impact.

Acknowledgements

This work was supported by funding from the Australian Government through Meat & Livestock Australia (MLA) under project code P.PSH.1286, Accelerating the Adoption of Satellite Assisted Forage Budgeting Across Northern Beef Businesses. The authors gratefully acknowledge the collaboration between MLA and Cibo Labs in developing and launching the Australian Feedbase Monitor. We thank the European Space Agency (ESA) for providing open access to Sentinel-2 satellite data and all the farmers who generously shared their site-based total standing dry matter (TSDM) measurements. We also acknowledge the valuable contributions of the Food Agility Cooperative Research Centre (CRC) through projects such as the Rangelands Carbon project and the ForageCaster project, which have advanced the development and application of technologies and data relevant to this work.

XII INTERNATIONAL RANGELAND CONGRESS AUSTRALIA 2025

Collaborative intelligence: AI-driven decision support for beef production

Wilson, CA.[1]; Naseem, U[2]; Zhang, Z[3]; Lu, H[3]; Tao, L[3]; Hay, R[1]; Everingham, Y[1]

[1] James Cook University, Townsville, Australia; [2] Macquarie University, Sydney, Australia; [3] The University of Sydney, Sydney, Australia

Key words: Beef production; Domain-specific AI; Collaborative intelligence; AI decision support; Agricultural innovation

Abstract

The agricultural industry is confronted with an ever-expanding array of innovations, technologies and scientific knowledge. Despite the availability of these solutions, the knowledge exploration process is time-consuming and cognitively demanding due to the volume and variability of information – this often leads to inconsistent advice, non-adoption, or suboptimal decision-making. BeefVantage aims to bridge this gap by providing a tailored AI-powered decision support system designed specifically for beef producers in Queensland – the first of its kind.

BeefVantage utilises advanced Natural Language Processing (NLP) techniques and fine-tuned Large Language Models (LLMs), focusing on trusted domain-specific data. This approach ensures high relevance and accuracy in its recommendations, moving beyond the limitations of generic AI tools, which often suffer from hallucinations and lack of domain-specific knowledge. The tool is in development, with a Minimum Viable Product (MVP) anticipated six months prior to the congress. The presentation will introduce the groundbreaking concept behind BeefVantage, detailing its initial validation processes, and explore the anticipated transformative impacts of this AI-driven tool on beef production.

BeefVantage represents a significant advancement in the application of generative AI in agriculture, tailored specifically to meet challenges faced by beef producers. By offering real-time, context-sensitive, actionable insights, it supports not only immediate problem-solving but also long-term strategies for sustainable and resilient operations. The scalability of BeefVantage suggests potential applicability to other regional contexts and agricultural sectors, promising broader impacts across rangelands.

Attendees will gain insights into cutting-edge generative AI applications in agriculture, understanding both the technological underpinnings and practical benefits. The session will invite discussion on how the collaborative intelligence of human experts and AI can be harnessed to improve the future of rangelands.

Introduction

The northern Australian beef production sector encounters distinct challenges in rangeland systems, where climate variability, environmental degradation, complex grazing land management, and market fluctuations place significant pressure on producers. While rapidly evolving agricultural technologies, innovations, and scientific knowledge offer potential solutions, they are often inaccessible or impractical for direct application (Knickel et al. 2009; Klerkx and Proctor 2013). The sheer volume and complexity of available information can overwhelm producers, complicating decision-making and leading to inconsistent adoption of innovations (Bronson and Knezevic 2016; Eastwood et al. 2019).

While tools like ChatGPT serve broad queries, they lack the precision and contextual relevance required for rangeland beef production, often generating plausible but inaccurate outputs—referred to as hallucinations—that undermine reliability (Bender et al. 2021; Balaguer et al. 2024). BeefVantage addresses these gaps by leveraging collaborative intelligence—a synergy of human expertise and advanced AI technologies—to provide tailored decision support. By integrating fine-tuned Large Language Models (LLMs), and advanced AI techniques, the system offers contextually relevant advice aligned with real-world on-farm challenges in rangeland systems.

Methods

Development followed a systematic workflow, beginning with problem definition and the collection and pre-processing of domain-specific data. The data was curated from trusted sources, including scientific journal papers, reports, case studies, fact sheets, conference proceedings, and industry guidelines. Multimodal content, such as podcasts and videos, was transcribed using Whisper (Radford et al. 2022) and integrated into the dataset.

Foundational models were identified and evaluated for integration with advanced AI techniques. Initial experiments focussed on fine-tuning Large Language Models (LLMs) (Ding et al. 2023) to generate nuanced domain-specific responses. Subsequently, advanced AI techniques were explored, included Retrieval-Augmented Generation (RAG) (Lewis et al. 2021) to retrieve relevant content from a vector database of domain-specific documents, and Graph Retrieval-Augmented Generation (GRAG) (Hu et al. 2024), which utilised a knowledge graph with 118,000 nodes and 508,000 edges to provide relational insights into critical topics. Additionally, an Agent Flow mechanism (Park et al. 2023) was also implemented to address knowledge gaps, conducting constrained web searches to deliver contextually relevant recommendations when the system could not generate a suitable answer.

Evaluation involved automated Q&A testing with 127 domain-specific question-answer pairs, assessing three metrics: relevance, groundedness, and helpfulness. All configurations were evaluated alongside foundational models. The highest-performing configuration was integrated into a Minimum Viable Product (MVP) with a user-friendly interface, allowing users to rate responses and provide descriptive feedback to support iterative improvements.

Results

BeefVantage demonstrates significant potential as a transformative decision-support tool for beef producers. The system functions as an interactive AI assistant, generating context-specific recommendations for challenges such as drought management, sustainable grazing practices, biosecurity measures, and reproductive efficiency. By providing accessible domain-specific knowledge, it enables producers to make informed, strategic decisions that address regional challenges and environmental demands.

Experiments with fine-tuning Large Language Models (LLMs) (Ding et al. 2023) demonstrated no significant improvement over the original Llama 3.1 model, leading to the decision to retain the original model. Performance evaluation indicated modest improvements across techniques explored, namely RAG, GRAG, and Agent, in terms of relevance, groundedness, and practical utility when compared to foundational AI models.

Combinations of techniques yielded mixed results. For example, integrating RAG with Graph RAG, despite its theoretical potential, resulted in decreased performance. This decline may be attributed to catastrophic forgetting, a phenomenon where a model loses general reasoning capabilities while acquiring new domain-specific knowledge (Luo et al. 2024). Ultimately, the highest-performing configuration was Llama-3.1-70B with Agent-RAG-Web, achieving a strong balance of domain relevance, groundedness, and practical utility.

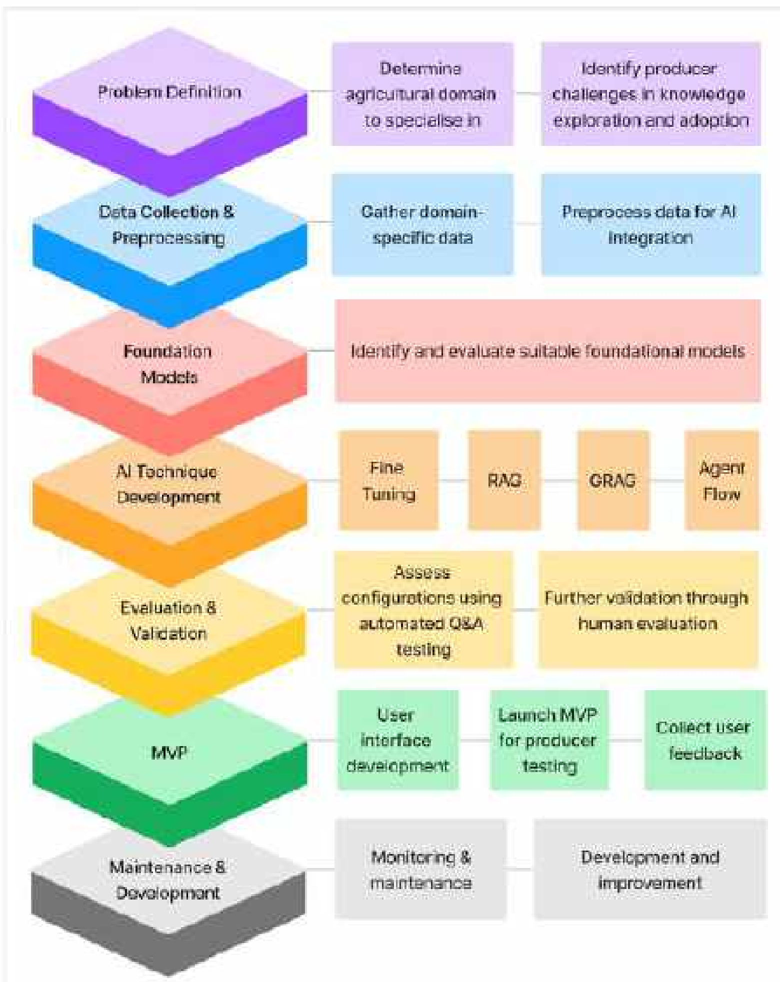

Figure 1. Development & Implementation Workflow

Key features of the MVP include a user-friendly interface with personalised accounts, saved chats, conversational memory, and the ability to download conversations. For example, producers can review previous queries related to grazing strategies, enabling continuity in decision-making. Preliminary testing has demonstrated its effectiveness in presenting complex scientific insights in an actionable format, successfully bridging the gap between academic research and practical applications.

Discussion

BeefVantage empowers producers to transition from reactive problem-solving to strategic planning by providing accessible knowledge and immediate, actionable insights. While trust in AI remains essential for widespread adoption in agricultural communities, transparent validation and producer-driven improvements can foster acceptance and encourage long-term engagement.

The system faces several challenges, including context window constraints, RAG/GRAG scalability, and adoption barriers such as digital literacy and connectivity literacy. Additionally, the platform includes a clear disclaimer, advising users to consult qualified professionals for veterinary or animal welfare concerns, ensuring clarity about its scope and limitations.

The next phase involves human evaluation to compare and validate results against automated metrics, ensuring practical utility. Feedback gathered upon the release of the Minimum Viable Product (MVP) will further refine the system, enabling continuous improvement and broader adoption. As foundational models and AI techniques continue to advance, significant improvements in system performance, scalability, and domain relevance can be expected, further enhancing the impact of tools like BeefVantage.

Future opportunities include adapting the system to other agricultural sectors and collaborating with technology partners to enhance capabilities, extend its relevance to full supply chain systems, and address broader agricultural challenges. Realising these possibilities will require sustained collaboration among researchers, producers, and industry stakeholders to overcome current limitations and amplify its impact.

Through the synergy of AI and human expertise, BeefVantage empowers producers to transform specialised knowledge into actionable insights, fostering sustainability, productivity, and resilience in rangeland systems. Its continued development and deployment hold the potential to redefine agricultural innovation, enabling beef producers to tackle pressing challenges and shape a more sustainable future.

Acknowledgements

This project was funded by the JCU Sandpit 2 Seed Fund with support from the TNQ Drought Hub. We thank the producers and industry experts who contributed to the human evaluation phase. Ethics approval was obtained from the JCU Human Research Ethics Committee (HREC).

Key words: ground cover; digital tools; rangeland management

Abstract

VegMachine.net is a free online platform for analysing long-term vegetation trends across Australian landscapes. Since its launch in 2016, the platform has been used for thousands of site-specific cover analyses, been a feature of numerous NRM and extension projects, and contributed to more than 30 peer reviewed studies. While VegMachine® has proven valuable to land managers, scientists, and environmental organizations, user feedback has highlighted potential improvements around more reliable data access, better mobile access and improved interface stability of the platform.

A recent upgrade to VegMachine has addressed these user requests by prioritising mobile accessibility and user experience. This upgrade includes a responsive mobile-first design, new tools for efficient data collection of user features, and data persistence for seamless use across sessions and when offline. Additionally, the backend infrastructure has been overhauled, resulting in improved data stability and robust access through a revamped Application Programming Interface (API) and improved data storage.

This paper discusses the improvements to the interface, backend API and improved data storage in detail. These changes will significantly improve the VegMachine user experience and make the application more accessible to a broader user base across Australia.

Introduction

Remote sensing provides land managers and researchers with a potentially useful source of time series vegetation data. However, accessing and interpreting these massive datasets requires specialised skills and processing capability. VegMachine is an online platform that simplifies this process by extracting and summarising subsets of these datasets, in a non-commercial, user-friendly way. Users can define an area of interest and then receive many years of vegetation cover data for that location without being required to download or process any datasets themselves.

After initial development in 2002 (Beutel et al., 2004), an expanded online version, VegMachine.net was launched in 2016 (Beutel et al., 2019). Since then, the number and variety of datasets provided has expanded to include a variety of monthly and seasonal vegetation cover products, persistent green cover, fire scars and rainfall. As well as supporting land managers to easily access data, the online version of VegMachine has been utilised for research projects in areas as diverse as grazing, ecology, hydrology and primary productivity. VegMachine has also been identified as a key digital resource for earth observation data by various state and national agencies.

VegMachine's success has occurred despite ongoing data service interruptions, outdated data access methods and limitations with the interface design. In recent years, VegMachine has been upgraded to address these issues. A new version of VegMachine will be released in 2025 with significant improvements.

Methods

Data Storage and Service Improvements

All datasets available through VegMachine are provided under the Queensland Government's open data policy. These valuable datasets are delivered via Terrestrial Ecosystem Research Network (TERN) infrastructure (TERN Queensland Node) on a non-commercial basis.

The infrastructure has undergone significant updates in recent years. The time series datasets have been transitioned onto a more stable platform and are now stored as Cloud Optimised GeoTIFFs (COGs) within an OpenStack Swift object-based storage system. Additionally, the GeoServer instance, providing Web Mapping Services (WMS), has been reconfigured to improve stability and data discoverability. Web Mapping Service Tiles (WMST) have also been implemented for scalability. This new architecture enables efficient data access within the updated VegMachine API and will significantly improve the stability and reliability issues previously experienced by VegMachine users.

Application Programming Interface (API) Redevelopment

The VegMachine API specialises in extracting vegetation data from time series raster files. Upon receiving a polygon, and a specified time series dataset, the API rapidly returns spatial summary statistics for each date, including monthly rainfall (Scarth et.al, 2017). The API is hosted on Digital Ocean virtual machines, supported by the Joint Remote Sensing Research Program (JRSRP). The machines have fixed capacity and lack scalability, so the speed of the API depends on efficient asynchronous data access rather than computing power.

The previous API relied on the use of WMS to enable asynchronous access. In a significant redevelopment, the API has been implemented as a custom Python package (JRSRP, 2024 (https://gitlab.com/jrsrp/sys/asyncog)) designed to asynchronously extract information directly from the COG files via an HTTP session. HTTP range requests minimise the amount of data transferred by spatially constraining the data. Directly accessing the underlying COGs additionally eliminates restrictions on data types that are inherent in WMS.

The VegMachine API also utilises raster overviews to reduce the volume of data read and processed. Overviews are resampled versions of the data at coarser resolutions. While employing overviews typically yields an unbiased estimate of the spatial mean, reducing raster resolution can also decrease variance within the data, as extremes in pixel values tend to be averaged out (see Figure 1). This smoothing effect may obscure the variability present in the original data, especially for larger regions. The level of resampling is determined by an input parameter in the API, which users can adjust. Currently, the API does not provide users with information about overviews or the resampling level, but this functionality will be made available to advanced users with the 2025 release of VegMachine. The VegMachine developers are also considering adapting the interface to allow users to opt for increased precision at the cost of processing speed.

Figure 1. The effect of raster resampling in VegMachine on the bare ground minimum-maximum range (blue and orange regions) for a larger property (~90,000 ha) is shown. Data variability reduces with increasing site area because VegMachine utilises coarser resolution rasters for large-scale analyses to ensure timely processing. Mean values remain unbiased (represented by the dashed and dotted lines).

Interface redesign

To enhance the accessibility of the VegMachine site, the interface has been redesigned as a responsive mobile-first web application. This redesign will enable users to access the full suite of VegMachine tools on any device. The desktop interface retains all previous functionality (Beutel et al., 2019), and existing users should find the transition to the new site straightforward.

In response to user feedback, a wide variety of additional features have also been incorporated into the updated version of VegMachine (Table 1).

Table 1. Major additional functionality for new VegMachine.net version release.

New Functionality	Description
Interactive Digital Cadastral Database (DCDB) overlay	Allows Queensland users to select a lot on plan to use as an assessable feature.
Enhanced download capacity	Downloads now include the assessed features as a vector file.
Persistent data storage	Vector map features from previous sessions are retained on refreshing the application, until manually deleted.
Advanced custom chart	Allows users to select three data series statistics from all available product statistics and create a custom chart.
‘Point’ features	Instant 1 ha circle feature creation, in addition to user drawn polygons.
GPS logger with offline capability (mobile only)	Allows users to record location as a point using device GPS. Functions offline for users out of internet range.

Results

The improvements have significantly stabilised the VegMachine platform, while the redesign of the interface has provided considerable additional functionality.

While most additional interface features are aimed at simply improving user experience, the advanced custom chart (Figure 2) and mobile interface (Figure 3) are significant additions to VegMachine functionality.

The advanced custom chart feature allows users to create a chart specific to their analysis from all available data products. Map and chart are synchronized, which facilitates the easy interrogation of the chart series against the underlying raster data. Figure 2 illustrates an example chart.

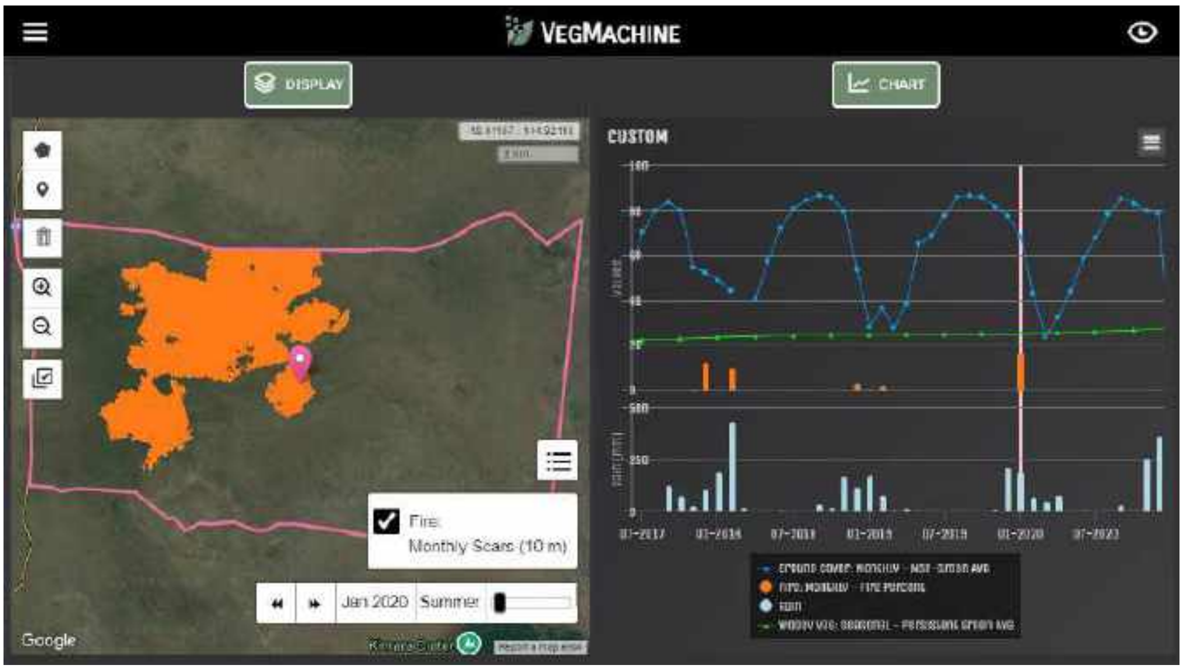

Figure 2. A screenshot of the updated VegMachine interface, showing output from the advanced custom chart feature, displaying three time series statistics (average non-green ground cover (blue), fire scar percentage (orange) and average persistent green (green)). Rainfall is also shown (light blue). By clicking on an observation in the chart, the synchronized map displays the relevant product for that date. In this instance a fire occupying 17 percent of the property for January 2020 is displayed.

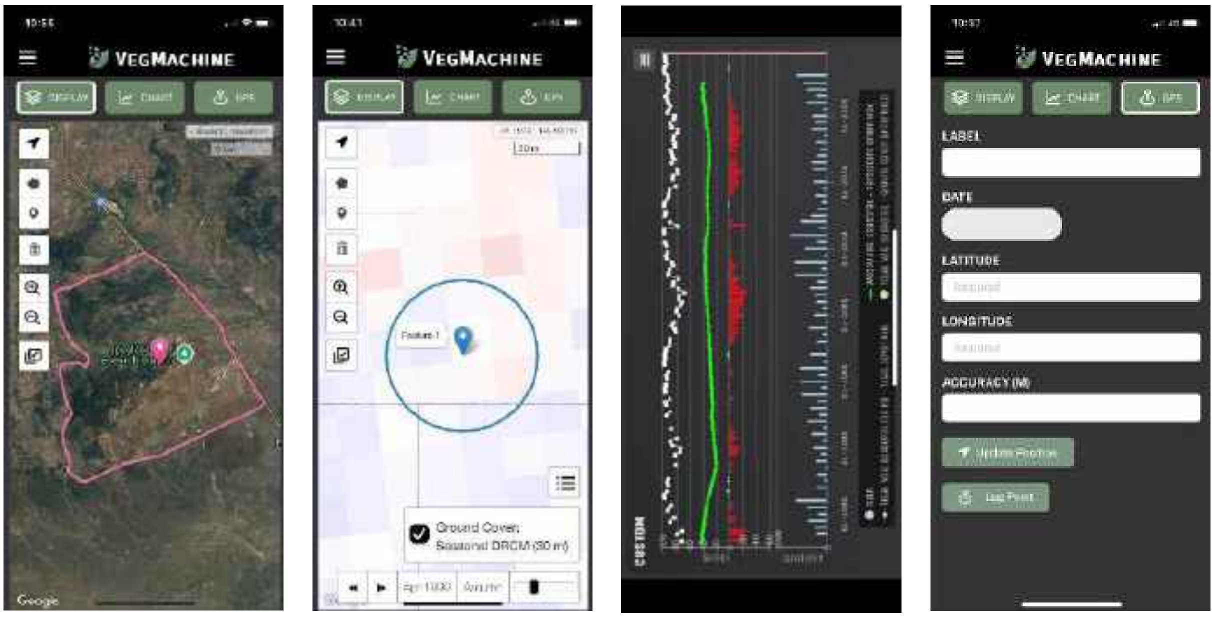
Two specific features have been added with mobile use in mind. The addition of point features (1 ha circles) will be useful for site assessments using mobile devices. The point features are optimised for straightforward application and 1 ha is a common site size. The GPS logger, with offline functionality, allows for easy point capture at locations even when out of internet range.

Discussion and Conclusion

VegMachine is a dynamically evolving platform undergoing continuous improvement. While major changes to its function and design are not anticipated for some time, incremental changes will continue to occur. Additional time series datasets will be considered for inclusion in the API and VegMachine interface if suitable. Additional publicly available APIs are expected to be developed, to meet user demand. These

APIs will be incorporated into VegMachine as additional tools and be made available for use in other 3rd party applications.

With these recent improvements, user demand is expected to increase. The degree to which the VegMachine API can scale to support additional demand, including the use of the API for 'batch' processing, is uncertain. However, VegMachine will continue to make valuable remote sensing time series data as easily accessible as possible to a broad cross section of users at no cost to them.



Map screen with a lot on plan displayed, selected from an interactive DCDB vector overlay.

Image time series overlay with time slider and point feature displayed.

Advanced custom chart with output optimised in landscape view.

Carbon exported in runoff from grazed semiarid lands in the Fitzroy Basin, Queensland, Australia

Bosomworth, B[1]; Lim, Y[1]; Wellham, R[1]

Key words: Great Barrier Reef; erosion; organic carbon; water quality

Abstract

The complexities of nutrient cycling in grazing systems are influenced by management practices and soil characteristics. Grazed land accounts for approximately 71% of the total land area in the Great Barrier Reef (GBR) catchment and plays an important role in soil organic carbon storage and cycling. This study investigates the effect of vegetative ground cover and soil properties on the export of carbon fractions in runoff from grazed land in the Fitzroy and Burdekin Basins of the GBR catchment under simulated rainfall.

Particulate organic carbon (POC) in runoff was driven by fluctuations in ground cover, where POC increased as ground cover declined. Soil type and texture, specifically clay fractionation, also contributed to the export of POC. In contrast, dissolved organic carbon (DOC) exports were independent of ground cover condition and instead linked with soil type; these being Dermosols, Sodosols, and Vertosols. Clay content less than 50% in the parent soil influenced DOC load, especially as an interaction with ground cover. The enrichment of DOC in runoff as clay increased and ground cover decreased suggests soil type, and associated texture properties, facilitate DOC mobilisation, and is enhanced by the disaggregation of soil particles as driven by the erosive action of raindrops and overland flow.

Raindrop impact, runoff, and entrainment of sediment are the primary drivers for POC losses, particularly where ground cover is scarce. However, the presence of DOC in runoff is influenced by the inherent characteristics of the surface soil. Interestingly, the organic matter content of the surface soil had little influence on the carbon fractions in this study. These findings highlight the importance of vegetative management in reducing POC losses from hillslopes through runoff. The lateral movement of soil organic carbon because of depletion in POC and DOC is an important aspect of the terrestrial carbon budget.

Introduction

Soil plays a central role in regulating the global carbon cycle, storing approximately 300 times the equivalent emissions from fossil fuels as soil organic carbon (Schulze and Freibauer 2005). As the largest terrestrial carbon pool, soil contains up to three times more carbon than the atmosphere and vegetation, making it a critical component of climate regulation and ecosystem functioning (Jobbágy and Jackson 2000;

Lal 2003). Research has discovered that agricultural practices have caused a decline of organic carbon from terrestrial systems (Kirschbaum et al. 2008; Thornton and Shrestha 2021). Organic carbon is an integral component of soil fertility and marine ecosystems, and understanding its fate through the hydrological cycle is receiving attention in research (Lal 2005; Berhe et al. 2007; Garzon-Garcia et al. 2015; Burrows et al. 2023).

Coastal waters of the GBR, Australia, showed an increasing trend of POC and DOC over a twelve-year period from 2005 to 2017 (Lønborg C. 2016; Waterhouse et al. 2018). Thornton and Elledge (2022) observed that heavy grazing pressure significantly increased the amount of runoff above that attributed solely to land use change, thus increasing the amount of sediment (including POC and DOC) being exported. The erosion of fine sediment is well documented from grazing lands and is associated with carbon both in runoff and as a component of declining soil fertility (Thornton and Shrestha 2021; Elledge and Thornton 2022; Thornton 2022).

End of catchment sediment loads are exacerbated by runoff and erosion processes, and contribute significant nutrients, including carbon, to stream systems and the marine environment (Ludwig et al. 1996; Bianchi 2011; Garzon-Garcia et al. 2015; Bainbridge et al. 2018). Greater understanding of terrestrially generated organic carbon loads will help quantify exports to the GBR (Lønborg C. 2016; Nachimuthu and Hulugalle 2016; Bainbridge et al. 2018), especially considering grazing is a significant portion of land use in the GBR catchment (71%). This study documents the mobilisation of POC and DOC in runoff from plot-scale rainfall simulation trials on grazing land in two GBR catchments.

Methods

The soil types included in this investigation are classified as Dermosols, Sodosols, and Vertosols, and represent 67% and 19% of the soils found in the Fitzroy and Burdekin Basins under grazing, respectively. The Fitzroy and Burdekin are the two largest basins in the GBR catchment, which combined, represent 70% of the total catchment area. Data was collected *in situ* on hydrologically bunded plots for each soil type under simulated rainfall with various ground cover conditions. Rainfall intensity applied averaged 81 mm/hr across 89 plots. Runoff from these sample plots (1.7 to 3 m^2) was collected from a galvanised flume draining into a connection pipe. Sample collection, water quality and soil chemical analysis methods are outlined in detail in Bosomworth et al. (2018), Bosomworth (2022), and Cowie et al. (2013). A two-way ANOVA was used to examine the effects of ground cover, clay, and silt content on POC and DOC. For POC data, analysis was performed on log-transformed to meet normality assumptions.

Results

Particulate Organic Carbon in Runoff

Ground cover had a significant influence on POC loads ($P<0.001$) where increased ground cover was associated with decreased POC loss. A similar effect was associated with the presence of clay ($P<0.03$) (Figure 1). Silt had no statistical effect ($P=0.2$). Soil type also had a significant effect ($P<0.001$), particularly where there was a high percentage of fine fractions in the parent soil. Where ground cover was <10%, Sodosols exhibited the highest mean POC load (28.9 kg/ha) followed by Vertosols (23.5 kg/ha) and Dermosols (6.0 kg/ha). As ground cover exceeded 10% total cover, POC loads decreased significantly by up to 88%, depending on soil type. POC was 2 to 99% of the total organic carbon fraction depending on soil type, ranging from 2 to 82% for Dermosol, 62 to 99% for Sodosols, and 2 to 99% for Vertosols. Soil organic matter in the parent material was not significant for POC load.

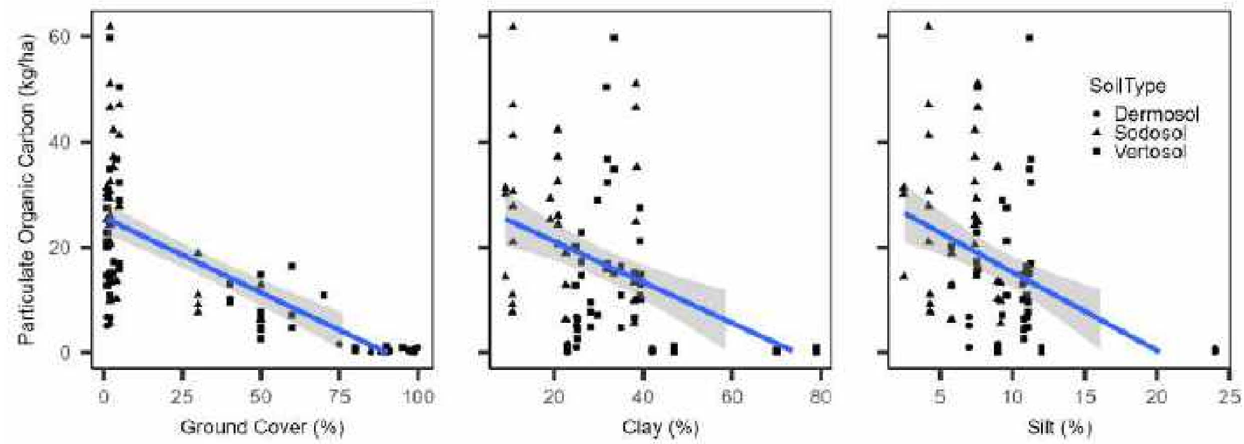

Figure 1: Particulate organic carbon (POC) loads in runoff (kg/ha) and the relationship to ground cover (left) and fractions of clay (centre) and silt (right) in the parent soil. Data points represent raw observed values, with the trendline based on log-transformed data to meet normality assumptions for statistical analysis.

Dissolved Organic Carbon in Runoff

Ground cover had no significant effect on loss of DOC in runoff (P>0.8) (Figure 2). Clay content was marginally significant (P=0.06), and silt content had no effect (P>0.2). Soil type was the main driver for DOC loads (P=0.002). An effect between ground cover and soil type was significant for DOC loads (P<0.001). Results suggest as clay fractions in the soil increase, the DOC loads tend to increase. However, once clay exceeds 50%, an inverse relationship was found. Where soils had <50% clay, clay content had a significant effect on DOC load (P<0.001). DOC was 1 to 98% of the total organic carbon load, ranging from 18 to 98% for Dermosol, 1 to 38% for Sodosols, and 1 to 98% for Vertosols. Soil organic matter in the parent material was not significant for DOC load.

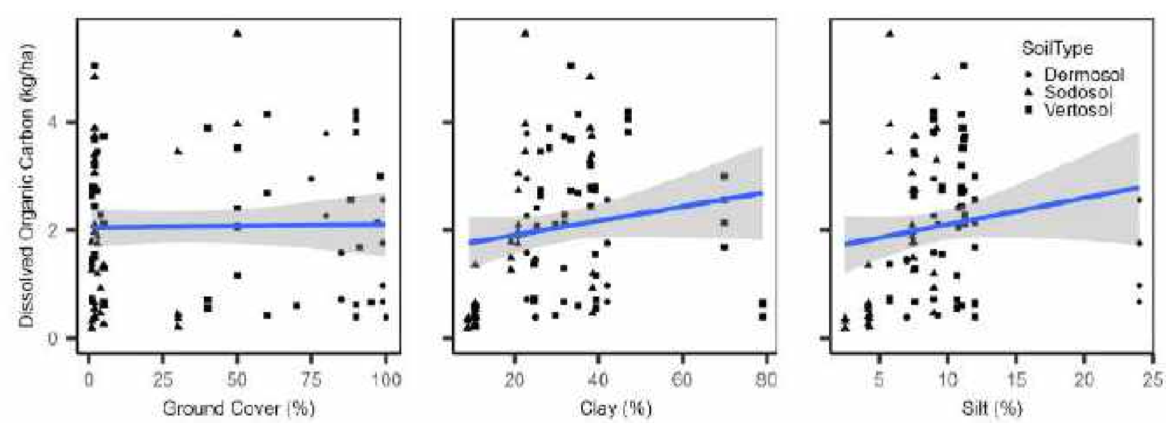

Figure 2: Dissolved organic carbon (DOC) loads in runoff (kg/ha) and the relationship to ground cover (left) and the fractions of clay (centre) and silt (right) in the parent soil.

Discussion

POC mobilisation in runoff was driven by erosion processes including raindrop impact and subsequent sediment entrainment. Where there was minimal vegetative protection, these processes facilitated the detachment and transport of fine soil particles, thereby increasing sediment and associated POC loads.

Managing ground cover will influence the contribution of this labile fraction of organic carbon. Many studies have shown variation in ground cover because of agricultural impacts such as grazing is strongly related to sediment export (Bosomworth et al. 2018; Thornton and Elledge 2021), and our results reinforce the importance of cover.

DOC mobility is primarily driven by soil type and the detachment and transport of finer particles associated with the parent soil. DOC loads are also influenced by the interaction between bare ground and clay fractions present in the *in situ* soil. Managing the DOC contribution isn't as easily achieved as it is for POC because of the variable nature of soil texture; however, increasing ground cover reduces fine particle detachment from raindrop impact and will impede both POC and DOC export.

The soils used in this study were located within the Fitzroy and Burdekin Basins, which, combined, represent 70% of the GBR catchment, from which 1300kt of fine sediment is exported annually (Prosser and Wilkinson 2024). Fine sediments, <20 µm, are easily suspended and transported, which includes the DOC fraction. Studies by Bainbridge et al. (2012) show that particles <16 µm are capable of sustained suspension and discharge from the end-of-catchment well into the Reef lagoon.

Packett (2017) showed that rainwater also serves as an additional source of DOC which could have impacts on the GBR, but also the terrestrial carbon pool. While concentration of DOC in rainfall from that study (range 0.7 to 2.3 mg/L) is lower compared to the mean soil-derived DOC reported here (8.1 mg/L; range 0.9 to 22.4 mg/L), its contribution to the total carbon budget should not be discounted. Given the nature of eroded organic fractions, which are prone to rapid mineralisation, quantifying their contribution in runoff from GBR catchments would provide further important insight into the carbon budget.

Ecosystem integrity index (EII) in ranchers of the "grass management" project in Uruguay

Cáceres Bentancor, D [1]; Laborde, J [1]; Orihuela, D[1]; Sancho, D[1]; Beretta, A[1]; Pereira Machín, M[2]

[1,2]Ministry of Livestock, Agriculture and Fisheries, Constituyente 1476, Montevideo, Uruguay; [2]Institute Plan Agropecuario, Br. Artigas 3802, Montevideo, Uruguay.

Key words: Grassland; conservation; index; livestock

Abstract

Grasslands cover about 60% of Uruguay and are the main forage for cattle and sheep production. This ecosystem and the other natural resources of livestock systems show great variability in their conservation status and little information is available. The Ecosystem Integrity Index (EII) is an indicator that assesses the state of a specific ecosystem under agricultural use, with reference to an optimal state that should be established for the ecoregion. Its application involves a qualitative and quantitative visual assessment, it has a scale of points (from 0 to 5) that includes four aspects: vegetation structure, species diversity, soil erosion and condition of watercourses and riparian zones. We carried out the EII in 12 ranches distributed throughout Uruguay, as part of the Grass Management Project of the Institute Plan Agropecuario, in the spring and summer of 2021 and 2022, years with below-average rainfall. A total of 10,808 hectares were studied. The EII showed different starting situations among the ranches. Within ranches, the EII showed differences between plots, and plots also showed differences in index composition. The EII was able to assess the conservation status of livestock systems in a simple way. The results made it possible to objectively characterise, target and localise restoration and conservation activities and make them more effective. It is planned to repeat the indicator at the end of the project to compare the ranchers' assessments.

Introduction

Uruguay is included within the grasslands of the Río de la Plata (Soriano, 1991), where they occupy 60% of the territory and are the main nutritional support for livestock production. Livestock systems present great variability in the state of conservation of grasslands and other ecosystems that need to be evaluated. To meet this objective, the Ecosystem Integrity Index (EII) was developed within the framework of the extension project of the Institute Plan Agropecuario (IPA) called Grass Management Project.

The EII is a point scale index (from 0 to 5) that includes four aspects: vegetation structure (VE), species diversity (SP), soil erosion (S) and condition of watercourses and riparian zones (RZ) (Figure 1). The index evaluates the state of a specific ecosystem under agricultural use, referring to an optimal condition to be established for the ecoregion (Blumetto et al., 2019). Its application involves a qualitative and quantitative visual assessment. The value is calculated for each paddock and an overall value weighted by the size of each paddock using the following equation:

$$EII = \sum_{n=1}^{n} \frac{(VE_i + SPp_i + S_i + \ RZ_i\ )APi}{4RA}$$

Fig 1. Where, VEi = vegetation structure score for paddock i, SPpi = species presence score for paddock i, Si = soil score for paddock i, RZi = riparian zone score for paddock i, APi = area of paddock, and RA = total ranch area, adapted from (Blumetto et al., 2019).

Methods

The EII was obtained in 12 ranches. The survey was carried out in the springs and summers of 2021 and 2022, totalling some 10,808 hectares distributed throughout Uruguay. Four ranches were selected for a second evaluation in the spring of 2024.

During the years 2021 and 2022, there were negative anomalies in precipitation indicators in all livestock regions of the country (MGAP, 2023), an aspect that is being reversed in the spring of 2024 (INUMET, 2024).

The relation between land use and the values of EII and they components was evaluated by regression coefficient. The general comparison between years of the EII and its components was performed by paired two-tailed t-test. The comparison within each ranch was performed by Fisher's test, the measurement site effect was considered a random effect, and the difference was significant when the p-value was less than 0.05.

Results

The Ecosystem Integrity Index and its four components are presented separately for each facility.

Table 1 Ecosystem Integrity Index and its components by ranches at the beginning (2021 and 2022) and at the end (2024).

†: Mean value and between parentheses the standard deviation. ‡ The letters indicate comparison of means between years for the same variable and ranches, the procedure of different means test of Fisher LDS was used whit alfa = 0,05.

In the evaluation 2021/2022 the average EII of the 12 ranches was 3.1, a standard deviation of 0.31 and a variance of 9%. On average, the EII had a significant increase of 0.10 points from 2021/2022 to 2024, in the ranches evaluated in both instances. The increased observed to VE was no significant (0,43). To the components RZ, S and SP, the means values had a significant increase of 0.05, 0.14 and 0.15 respectively.

The proportion of grassland increase the EII values (regression coefficient = 1.05, p-value=0.02), the VE values (regression coefficient = 1.71, p-value=0.02) and SP values (regression coefficient = 1.81, p-value=0.02). No significant coefficient regression coefficient was observed between proportion of grassland and S or ZR.

Fig. 2: EII per ranch and per paddock

Discussion

The EII obtained was above its mean value in all the ranches, showing different starting points between ranches and differences in the internal composition of the index (Table 1). On the other hand, differences were observed within each ranch; these findings allow focusing and locating restoration and conservation measures, and to this end maps were generated for each cattle farmer (Figure 2).

On the other hand, the data on land use in each ranch were related by regression with the EII obtained, resulting those ranches with a higher proportion of grasslands obtained a higher value of EII, this was explained by its positive and significant coefficient regression of the structure (VE) and species (SP) components, which highlights the environmental importance of grasslands for livestock systems.

In the four ranches where the index was performed again in 2024 the results indicate that in general terms there was a positive evolution of the overall EII and also in most of its components (p value<0.05), this coincides with what was found by Blumetto et al., 2019. and shows a positive effect of the project on the environmental quality of the ranches, although there may also be an effect of the change in the rainfall regime existing in the period.

Conclusions

The EII was able to evaluate the conservation status of livestock systems in a simple way. It allowed characterizing the different systems and having objective criteria to locate and focus restoration and/or conservation actions. The grassland showed a great importance in the environmental quality of the ranches. Moreover, the index showed significant changes between the beginning and the end of the project in four selected ranches, which shows a positive effect of the project and/or an effect of improved rainfall, it would be important to continue monitoring these ranches.

Acknowledgements

To the 12 ranches who allowed us to enter their farms to carry out the necessary surveys, to the authorities and board of directors of the IPA for their confidence in the technical team of the DGRN of the MGAP to execute this Project and allow us to present it at this congress. To Oscar Blumetto of INIA for the training and technical support.

Key words: virtual fence; precision agriculture; livestock management; professional development

Abstract

Virtual fence (VF) is an expanding technology used on rangelands around the world. The system uses invisible barriers established by Global Navigation Satellite System (GNSS) coordinates to influence livestock movement without a physical fence. VF systems use a combination of auditory and electrical cues (i.e., beeping noises, benign electrical shocks) that originate from a wearable, GNSS-enabled VF collar. This emerging precision livestock management technology has the potential to change grazing systems by improving livestock control and distribution. Collars also generate livestock location data, which can provide information about grazing behaviour and support decision-making. Despite these opportunities, VF systems can be complicated and expensive to adopt. To address these challenges, researchers at the University of Arizona and the Southern Arizona Experiment Station have developed a digital Virtual Fence User Guide based on ongoing field trials at the University of Arizona's Santa Rita Experimental Range (Green Valley, Arizona, USA) in collaboration with the Rangelands Partnership (RP) and members of the Virtual Fence Working Group. Available on the RP's Rangelands Gateway (https://rangelandsgateway.org/virtual-fence), the guide includes practical information about VF adoption, learning modules, early adopter videos, recordings and handouts from past webinars, and answers to frequently asked questions. Tools for comparing costs between the various vendors and instructions on how to mobilize a base station to optimize coverage are also available. This comprehensive guide of digital support tools empowers land managers to effectively evaluate and use VF to improve rangeland management.

Introduction

Precision livestock management is becoming an increasingly appealing opportunity for land managers as climate change, severe drought, and unpredictable extreme weather events pose growing challenges for land managers on rangelands around the world. Virtual fence (VF) systems are precision management tools that use invisible barriers to manage livestock distribution on a ranch. When used with a grazing management plan, VF has the potential to change grazing systems by allowing novel influence over livestock movement with a combination of auditory and electrical cues (i.e., beeping noises, benign electrical shocks) that originate from a wearable GNSS-enabled collar (Antaya et al. 2024a). These systems rely on three interconnected components (1) software to draw VF boundaries on a digital map, (2) GNSS-enabled collars worn by livestock that deliver an auditory and/or electrical cue when an animal approaches the invisible VF barrier, and (3) base stations or cellular service to relay information about the invisible VF boundaries to the collars (Antaya et al. 2024a; Ehlert et al. 2024). While VF systems were first described decades ago, improvements in technology have brought VF to the forefront of ranching with the launch of several commercial VF systems by different vendors (Anderson 2007). However, as an emerging technology, there has been limited information available from unbiased sources to help land managers effectively evaluate and implement VF for sustainable rangeland management. As more VF vendors enter the market, interest and excitement over VF technology is likely to increase. Because of this, we developed an impartial VF outreach and educational resource so prospective users can make informed decisions before investing time and money in novel VF technology.

The challenge of finding accurate science-based rangeland information is the foundation of the Rangelands Partnership (RP), a group of rangeland professionals, agricultural librarians, and technology experts from across the United States (Hutchinson and Ruyle 2002; Hall et al. 2022). Since 2002, the RP has worked to bridge the gap between peer-reviewed content and on-the-ground land managers by maintaining an online portal called Rangelands Gateway (https://rangelandsgateway.org/). Rangelands Gateway provides access to a database of quality and peer-reviewed information related to rangeland ecology and management. The portal also provides access to new cutting-edge educational resources through diverse platforms including decision support tools and videos (Hall et al. 2022). The RP and Rangelands Gateway provide a unique opportunity to create and distribute information about VF.

Within Rangelands Gateway, the Virtual Fence User Guide (https://rangelandsgateway.org/virtual-fence) is designed to empower land managers to effectively evaluate and use VF for improved rangeland management by providing access to comprehensive information and resources. This article introduces the VF User Guide and describes the digital resources that it provides through diverse platforms including factsheets, videos, webinars, and support tools.

Methods

The VF User Guide is a digital resource created within the RP's Rangelands Gateway. The platform was designed to synthesize rangeland information and provide an opportunity to learn about emerging technologies through articles, factsheets, videos, webinars, and additional resources (Hall et al. 2022).

The primary resource in the VF User Guide is a collection of VF articles, called the *Foundations of Virtual Fencing*, based on real-world field trials at the University of Arizona's Santa Rita Experimental Range (Green Valley, Arizona, USA). Through a collaboration between the Marley Endowment for Sustainable Rangeland Stewardship, Arizona Cooperative Extension, and the Santa Rita Ranch LLC, researchers deployed a ranch-scale VF system (Vence™ CattleRider™ ver. 2 rev. c-g, Vence Corporation, San Diego, CA, USA) on the Santa Rita Experimental Range, a working research ranch, in 2021. From these early experiences, a variety of opportunities and challenges associated with VF adoption were documented. Additional early adopter experiences were gathered from the VF Working Group (VFWG), a community of practice primarily made up of researchers from USA land-grant Universities and non-governmental organizations formed to address knowledge gaps (Ehlert et al. 2024). Implementation and ongoing issues were documented and organized into overarching themes. With a diverse set of experiences and recurring problems, factsheets were developed to explain, offer solutions, and acknowledge the challenges of implementing VF so future users would be more prepared than the initial group of early adopters.

A multimedia approach was taken to develop the VF User Guide, incorporating learning modules, videos, webinars, and interactive decision support tools. Learning modules were collaboratively developed with VFWG members and created using Google Earth, an open access software. The intent was to provide prospective users with an instructional reference without needing access to the proprietary, vendor-specific VF software. This allows prospective users to understand what is required to set up and manage a VF system without having to first purchase a system. To share the experiences and insights of early adopters, the guide includes a four-part video series designed to help prospective users understand how others have integrated VF into real-world operations. Additional videos created by other VFWG members provide additional information on other relevant topics. Three webinars were held in fall 2024 and winter 2025 focused on adoption and implementation of VF. Webinar topics were developed based on feedback from prospective users. Recordings and handouts were posted online for open access. Finally, several interactive decision support tools were either created by University of Arizona researchers or identified and compiled from VFWG members. These include answers to frequently asked questions, resources about the financial impact of VF adoption, instructions on modifying a base station to make it mobile, and access to geospatial databases.

Results

The VF User Guide contains four primary sections to help prospective users make informed decisions about VF and improve the chances of initial success if they adopt the technology. These sections are factsheets, videos, webinars, and support tools.

Factsheets

The main function of the guide is to provide users with written information about VF that can be accessed at any time. The collection of science-based, peer-reviewed open-source factsheets are focused on the foundational information needed from start to finish, and include:

1. Basics of a VF system (Antaya et al. 2024a),
2. Economic viability of VF adoption,
3. Vital role of high-quality geospatial data (Antaya et al. 2024b),
4. Collar deployment recommendations,
5. Principles of livestock training and animal welfare considerations (Mayer et al. 2024a),
6. Strategies for collar management (Antaya et al. 2024c), and
7. Complexities and challenges (Mayer et al. 2024b).

Videos

The guide includes a variety of learning modules, early adopter videos, and other videos. Learning modules include (1) how to create a VF boundary on a digital map using VF terminology and (2) what factors to consider when placing a VF (i.e., quality of the digital map, buffer zones, fence design, water sources, and locations where VF is not appropriate). There is also a four-part video series that showcases the experiences and insights of early adopters across the USA. Additionally, videos created by VFWG members filled in knowledge gaps related to collaborations, land manager experiences, applications, animal reactions to collars, and tutorials.

Webinars

Recognizing the need for an interactive component, one-hour webinars were developed to focus on high-impact VF topics. The first webinar highlighted the basic components and compared the VF vendors available at that time. Building on this introduction, an application webinar focused on three real-world examples of how VF has been used to improve rangeland and livestock management. An economics webinar outlined the benefits, costs, returns over time, and tools to make informed decisions. Recordings and handouts are available in the VF user guide for future reference and continued distribution.

Support Tools

A variety of support tools were either created or compiled to help prospective users obtain the necessary information in one place. These items include:

1. Calculators to compare the cost of VF systems and physical fences under different scenarios,
2. Concise answers to frequently asked questions,
3. Instructions on how to mobilize a base station to optimize coverage, and
4. Direct links to USA-based geospatial databases.

Discussion, Conclusions, Implications

The VF User Guide aims to assemble comprehensive, unbiased educational and outreach materials to help land managers understand the complexities and challenges of applying an expensive, unfamiliar tool on real-world ranches. Collectively, the resources should help prospective users determine whether VF is a good fit for their unique operation and what to expect and prepare for during implementation. Without this information, land managers may miss opportunities to use VF to adapt to challenges or may misapply the technology, ultimately leading to frustrations when learning and using the technology.

As of 2024, there are four companies that manufacture and sell VF hardware and software in the United States. Whenever possible, resources in the guide describe VF components in a vendor neutral fashion to avoid bias toward a particular vendor. Most resources also include a disclaimer indicating the University of Arizona and RP do not endorse a specific product. Thus, recommendations are general and may lack the specificity required for a particular vendor. Additionally, as the technology evolves over time, suggestions may slightly misalign with the VF vendor recommendations. The guide is not a replacement for manufacturer instructions. Instead, the VF User Guide is intended to provide non-vendor specific practical guidance based on our experience and the experiences of those in the VFWG.

VF is rapidly evolving as interest in precision livestock management technology increases and wearable technology improves. There is a critical need for more independent, University-led research to understand the capabilities of these systems to support rangeland stewardship and research findings must be shared so prospective users can make informed decisions. The VF User Guide is a platform to share research findings with diverse audiences. However, the guide is only useful if the resources available cover the spectrum of questions and concerns of real-world land managers. To stay up to date, we will continue to add relevant information to the guide. This will require continuing collaborations with the VFWG as well as creating new collaborations to amass open-source and public domain content. We hope the Virtual Fence User Guide on Rangelands Gateway will be the place to access unbiased, science-based information to make informed decisions about VF.

Acknowledgements
Authors would like to thank the Rangelands Partnership for their feedback in developing the Virtual Fence User Guide. The development of the Rangelands Partnership's Rangelands Gateway was supported by the Renewable Resource Extension Act Program from the U.S. Department of Agriculture (USDA) National Institute for Food and Agriculture (NIFA) (ARZT-5705001-E12-505). Likewise, we value the contributions of all current and past individuals on the University of Arizona's VF team including Andrew Antaya, Joslyn Beard, Carter Blouin, Brett Blum, Dari Duval, Jose Quintero, Brandon Mayer, and George Ruyle. We are grateful to the University of Arizona's Communications & Cyber Technologies lab and Landmark Stories for their technical expertise. We appreciate the contribution of the Virtual Fence Working Group to the advancement of virtual fence knowledge. Special thanks to the Santa Rita Ranch LLC. Animal Ethics protocol approved by the University of Arizona's Institutional Animal Care and Use Committee (IACUC; protocol number 2021-0710). This material is based upon work that is supported by USDA NIFA through the Western Sustainable Agriculture Research and Education program (award no. 2021-38640-34695; project number WPDP22-016). This work is also supported by the USDA NIFA Agriculture and Food Research Initiative (AFRI) Foundational and Applied Science Program: Inter-Disciplinary Engagement in Animal Systems (award no. 2022-10726). Additional funding was provided by the Arizona Experiment Station, the Marley Endowment for Sustainable Rangeland Stewardship, Arizona Cooperative Extension, and The Nature Conservancy.

Application of vegetation indices obtained from satellite images for the management of the Voisin rational grazing

Díaz-Ambrona, CGH[1]; Rodríguez, RG[2]; Montoya-Téllez, R[3]

Key words: Cattle; mediterranean climate; NDVI; pastures.

Abstract

Cattle ranchers have problems making informed decisions for the management of natural pastures. The lack of information ends up forcing the animals to be supplemented with external feed and forage. The degradation of natural pastures, climate change, and agricultural policies aimed to make farms more sustainable. Sustainability requires improving natural resource management techniques. Voisin Rational Grazing manages grazing time based on the critical leaf area index; it has been proposed as a sustainable alternative for livestock. This method is based on optimizing the productivity of pasture and livestock but requires constant plots monitoring. The objective was to estimate through remote sensing the evolution of growth, biomass, and other pasture management parameters, which facilitate decision making in the Voisin. A real case study was chosen. The farm has 240 ha in 81 paddies in 5 counties, and 1,703 ha of communal pastures in joint use for summer use. It is in the northern of Madrid, in Central Spain under Mediterranean climate. Sentinel-2 images were used between 2017 and 2020, the processing and calculation of the vegetation indices was carried out with Sen2Cor and QGIS. In the field, biomass was sampled, and images were taken and processed with QGIS and SW Maps. A wide variety of factors affect the farmer decision, making the dynamics of the pastures between the plots heterogeneous in phenology and production. The evolution of the vegetation indices follows the dynamics of the grass logistic curve. Vegetation indices seem appropriate to detect the point of maximum grass biomass gain, necessary to apply the Voisin. Plots that are being grazed at high instantaneous stocking density, characteristic of the Voisin, can be detected using vegetation indices. Also, it was appreciated how this grazing method allows rapid regrowth. We considered that remote sensing can facilitate the application of Voisin Rational Grazing.

Introduction
Rangelands ecosystems cover more than a third of the world land surface, supporting key ecosystem services and livelihoods. The main drive variables for sustainability of rangeland are climate change, temperature and precipitation, and social-economic trends (Herrara and Davies 2014; Gartzia et al. 2016; Sanz et al. 2021). Identifying critical factors and main sources of risk into the rangelands provide useful tools for the design of mitigation measures and other measures (Iglesias et al. 2016).

Rational grazing (Worstell and Voisin 2015), specifically the methodology developed during the 1950s by researcher and farmer André Voisin (whose surname is used to commonly refer to this methodology as Rational Voisin Grazing, or RVG), is proposed as a grazing system to be implemented. While there are numerous grazing methodologies that could be considered rational—or at least account for both the development of the animal and the pasture—they all share the same foundation.

The main target of this grazing system is to optimize the production of the grazing animal and the productivity of the grazed pasture, which entails finding an optimal balance between meeting the needs of both the livestock and the pasture simultaneously. For the grazing animal, the aim is to maintain an adequate diet for the livestock in the pasture. This requires meeting the animals' needs in sufficient quantity and quality to achieve appropriate production parameters, which can only be reached if the animals' health and welfare are ensured (Pinheiro Machado et al. 2021). Our objective was to estimate through remote sensing the evolution of growth, biomass, and other pasture management parameters, focus on apply vegetation indices to facilitate decision making in the Voisin Rational Grazing systems.

Methods
We selected a rangeland from central Spain. The livestock operation under study is located at the northern mountain of the Community of Madrid. The lower parts of this area feature gentle topography, situated around 1,000 meters above sea level, while the highest peaks reach up to 2,000 masl. The operation runs a surface area of 240 hectares divided into 81 plots, of which 25 hectares equipped with irrigation. Also, it runs communal pastures covering 1,703 hectares grazing between March and October (as summer pastures). The operation includes 126 nursing cows of the native "Berrenda en Negro" Spanish breed (average 550 kg LW/cow), which are crossbred with Charolais bulls for industrial purposes.

The annual average temperature recorded is 11.3 °C, with the minimum average temperature of 4 °C in January and the maximum of 20.7 °C in July. The annual average rainfall is 637 mm, with November being the wettest month (90.7 mm) and August the driest (18.1 mm). This rainfall and temperature regime results in a dry period lasting four months: June, July, August, and September. Regarding the frost period, estimates using the Papadakis method indicate a medium frost-free season from April 21st to November 4th. The soils in the area are classified under the USDA Soil Taxonomy as Inceptisols in higher areas and Entisols in the valley floor. The soil pH is moderately acidic, ranging between 5.78 and 6.3, and the soil organic matter content varies from 0.66% to 4.3%.

In the field, biomass was sampled, data was gotten from the farmer land book and from field samples. Up to seven different types of pastures have been identified, also the agroforestry of ash (*Fraxinus angustifolia* Vahl.) and oak (*Quercus pyrenaica* Willd.), because they constitute a considerable source of food at the end of summer and beginning of autumn, when sometimes there is no grass regrowth and therefore, they represent an alternative source of great importance. The habitats present according to European Union Habitats Directive (Council Directive 92/43/EEC) are 6220 (*Festuco amplae-Poetum bulbosae*); 6310 (*Juniper oxycedri-Quercetum rotundifoliae pastures*); 91B0 (*Querco pyrenaicae-Fraxinetum angustifoliae*) and 92A0 (*Rubo-Salicetum atrocinereae*). During 2020, two types of management were studied: continuous grazing (in which areas that were being grazed during sampling were determined) and rotational grazing (areas that were excluded from grazing).

Following a literature review, seven vegetation indices have been chosen that have already been used to relate them mainly with grass biomass (Table 1).

Table 1. Vegetation indices obtained according with the literature for vegetation quantity or quality that can be calculated using pairs of Sentinel-2 bands.

Vegetation indices	Acronyms	Equations
Normalized Difference Vegetation Index	NDVI	(B08 - B04) / (B08 + B04)
Enhanced Vegetation Index	EVI	2.5 × (B08 - B04) / [(B08 + 6×B04 - 7.5×B02) + 1]
Renormalized Difference Vegetation Index	RDVI	(B08 - B04) / √(B08 + B04)
Green Normalized Vegetation Index	GNDVI	(B08 - B03) / (B08 + B03)
Sentinel 2 Red Edge Position	S2REP	705 + 35 × ([(B07 + B04)/2) - B05] / (B06 - B05)
Red-Edge Normalized Difference Vegetation Index I	RENDVI I	(B06 - B04) / (B06 + B04)
Red-Edge Normalized Difference Vegetation Index II	RENDVI II	(B07 - B04) / (B07 + B04)

*Sentinel-2 layers bands (ESA 2021): B02 (490 nm), B03 (560 nm), B04 (665 nm), B05 (705 nm), B06 (740 nm), B07 (783 nm), and B08 (842 nm).

Sentinel-2 images were used between 2017 and 2020 from Copernicus Open Access Hub to calculate vegetation indices and to monitor rangeland pastures. The processing and calculation of the vegetation indices was carried out with Sen2Cor 02.08.00 and QGIS 3.16.1. All data was processed with QGIS and SW Maps. A wide variety of factors affect the farmer decision, making the dynamics of the pastures between the plots heterogeneous in phenology and production.

Results

Pastures biomass

The farmland displays a wide variety of factors leading to heterogeneity in the phenology and production of pasture across plots. Pasture productivity ranged from 1,563 kg DM/ha in non-irrigated plots (2017) to a maximum of 4,108 kg DM/ha in irrigated plots (2020), with an average of 2,686 kg DM/ha in rain-fed plots and 3,174 kg DM/ha in irrigated plots.

The evolution of the vegetation indices

The evolution curves of the vegetation indices (VIs) showed that all indices detected changes in pasture senescence. Figure 1 illustrates how the senescence of irrigated pastures is delayed compared to non-irrigated pastures.

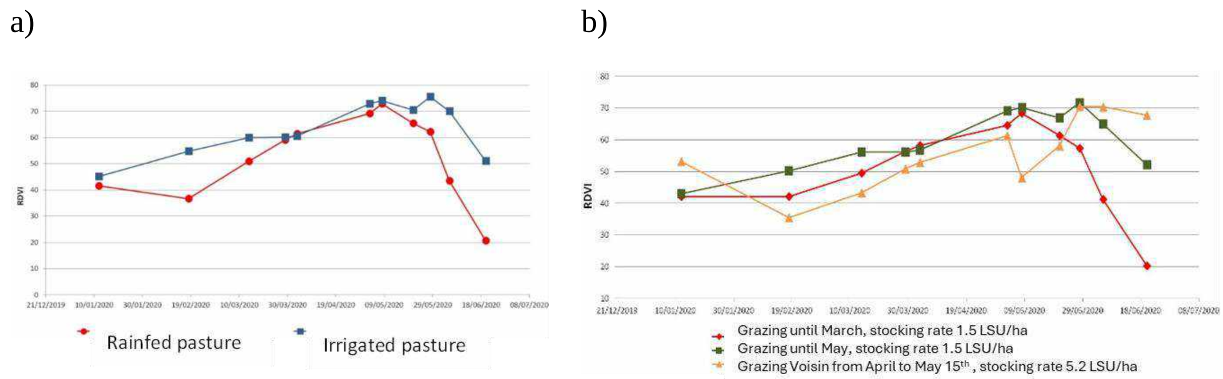

Figure 1. a) Evolution of Renormalized Difference Vegetation Index RDVI in rainfed areas and under irrigation during pasture growth periods in from winter 2019 to summer 2020; b) Evolution of Renormalized Difference Vegetation Index RDVI with different pastures management from winter 2019 to summer 2020.

When examining the effects of grazing, clear changes were only observed in plots with high instantaneous stocking rates (5.2 LSU/ha) according to Voisin. In contrast, plots with low stocking rates (1.5 LSU/ha) showed no significant differences between grazed and reserved plots (Figure 1b). From Figure 1b, it can be seen what effects are expected from PRV through the plot grazed for a short time at a high loading: the estimated production was 3,060 kg DM/ha compared to 4,060 kg DM/ha despite having been thoroughly grazed and reserved for a period at least two weeks less than the plot reserved in May. The application of rational Voisin grazing improved grass production by 24% to 76% depending on the type of grass and management (Table 2).

The evolution of VIs follows the same logistic curve dynamic as pasture growth, indicating their suitability for detecting the point of maximum biomass gain. Specifically, the RDVI index was selected for its higher sensitivity to phenological and management changes.

Table 2. Pasture productivity (kg DM/ha year) in the current and Voisin. Current management continuous grazing (in which areas that were being grazed during sampling were determined) and rotational grazing (areas that were excluded from grazing)

Management	**Current grazing** **kg DM/ha year**	**Rational Voisin Grazing** **kg DM/ha year**	**Pasture gain** **kg DM/ha year, (%)**
Continuous grazing (rainfed)	2,750	4,825	2,075 (76%)
Rotational grazing (rainfed)	3,625	4,825	1,200 (33%)
Rotational grazing (irrigated)	4,934	6,134	1,200 (24%)

Regarding the correlation of the evolution of vegetation indices with biomass in summer, it has been found that this is more adjusted in the grazing paddocks that have not been grazed since March for the set of years 2017-2019-2020. Therefore, considering the period within each season between March and the date with available satellite image following that with which the highest value of May is obtained and a linear adjustment; the cumulative or integral of the IV that has the best correlation with the estimated biomass of the pasture is the EVI ($r^2 = 0.52$).

Discussion and conclusions

It has been demonstrated that vegetation indices can identify plots grazed with high instantaneous stocking rates, a key feature of the RVG system. Additionally, this type of grazing allows for rapid pasture regrowth, achieving satisfactory productivity compared to other management approaches. The RDVI appears to be the most sensitive index for detecting changes in pasture management and phenology, making it a valuable indicator for Voisin grazing management.

Following Sanz et al. (2022) vegetation indices time series could allow us to understand better the rangelands´ evolution and the effect of management in these trends. The biomass estimation results suggest that the relationship between biomass and the accumulated VI value throughout the growth season depends on the availability of satellite imagery, particularly during critical growth periods in spring when cloud cover can limit data availability.

The best vegetation index for estimating pasture biomass in this study was the EVI. While the results could be improved with more data and biomass sampling, the index can still be used for pasture management, considering its limitations. These limitations primarily relate to the reliance on final biomass data from long growth periods without grazing. Therefore, it is proposed to use RDVI for detecting changes in pasture (management, phenology, or rest periods) and EVI for estimating available biomass after reserving pastures for cutting.

Using optical remote sensing LAI for semi-natural grassland yields prediction in Noteć river valley

Goliński, P[1]; Golińska, B[1]; Czerwiński, M[1]; Dąbrowska-Zielińska, K[2]

[1]Poznań University of Life Sciences (PULS), Department of Grassland and Natural Landscape Sciences, Dojazd 11, 60-632 Poznań, Poland; [2]Institute of Geodesy and Cartography, Remote Sensing Centre, Modzelewskiego 27, 02-679 Warsaw, Poland

Key words: leaf area index; remote sensing; semi-natural grassland; yield prediction

Abstract

The aim of the study was to evaluate the suitability of LAI calculated from satellite data (LAI-sat) for semi-natural grassland yield prediction in Noteć river valley based on relations between in-situ ground measured yield indicators and LAI computed from in-situ values (LAI-cept) compared to relations between those indicators and LAI-sat data. The research was carried out in the years 2020-2023 within the project GrasSAT (www.grassat.eu) on semi-natural grasslands located in Noteć river valley (Wielkopolskie region in central-western Poland). Annual yield data were collected from ca. 150 ha of semi-natural grass vegetations located on organic soils used extensively for cutting raw material for conserved fodder. In each grassland, ground measurements were carried out in a representative 30 m × 30 m plot every 2-3 weeks during the growing season. Fresh and dry matter yield was determined from biomass samples collected using a quadrat frame. LAI-cept was measured using AccuPAR LP-80 ceptometer and LAI-sat was obtained from platform Weekeo based on Sentinel-2 satellite images at 10 m pixel resolution. Statistical analysis has shown that all the tested relations had high correlation coefficients. The accuracy between LAI and FM or DM was slightly higher for for LAI-cept than LAI-sat. The optical remote sensing LAI applied for semi-natural grassland yields prediction is an efficient method that can be used to monitor the productivity of grass communities located in riparian areas of river valleys. This can help in planning for agricultural practices, can be an efficient tool in decision support system of semi-natural grassland management, and offsetting financial risks on large scales.

Introduction

Leaf area index (LAI) is an excellent proxy for biomass estimation because it directly quantifies the amount of leaf surface area relative to the ground area, providing critical insights into the vegetation's photosynthetic capacity and overall health (Parker 2020). Since biomass is closely linked to the amount of photosynthetically active tissue, LAI serves as a reliable indicator of the total biomass present in an ecosystem (Dąbrowska-Zielińska et al. 2024). Additionally, LAI captures variations in canopy structure, density, and leaf area, which are essential factors influencing biomass accumulation. Its non-destructive measurement and correlation with other biophysical parameters make LAI a valuable tool for accurately estimating biomass across diverse vegetation types e.g. of grassland and rangeland (Reddersen et al. 2014). LAI can be measured using ground-based methods, but these approaches are time-consuming, labor-intensive, and difficult to apply at a regional scale. In the last few decades, remote sensing-based approaches which are endowed with high temporal resolution and the capacity for large-scale observation are increasingly used to estimate LAI. As reported by Reinermann et al. (2020), LAI is one of the most widely used index within the studies investigating grassland management with remote sensing data, just like NDVI and band reflectance values. Therefore, research towards practical applications of remote sensing-based LAI is needed to support grassland and rangeland growth modelling and appropriate management decisions.

The aim of our study was to evaluate the suitability of using optical remote sensing LAI for semi-natural grassland yields prediction in Noteć river valley.

Methods

The research was carried out in the years 2020-2023 within the project GrasSAT (www.grassat.eu). Reference data were collected on six semi-natural grasslands located in Noteć river valley (Wielkopolskie region in central-western Poland, one 52º89' N, 16º45' E, two close to each other 53º07' N, 16º92' E and three also located very close to each other 53º05' N, 17º10' E). Investigated area ca. 150 ha of semi-natural grass vegetations was located on organic soils used extensively for cutting raw material two times per year for conserved fodder (hay or haylage). As suggested by Crabbe et al. (2019), on each site, a 30 m × 30 m plot was randomly selected for in-situ ground measurements to encapsulate the resampled 10 m × 10 m spatial resolution of the Sentinel-2 imagery, allowing for a 10 m radius buffer around the 'central pixel' location for uncertainty in spatial registration of the image pixels. Field measurements were carried out every 2 to 3 weeks throughout the growing season. In this paper we investigated the hypothesis that the correlation between semi-natural grassland yield and different LAI obtained in-situ and from satellite is similar. The yield was represented by two indicators: aboveground fresh biomass (FM) and dry biomass (DM). On each site, the FM and DM yields were determined using quadrat frame method from the area of 0.5 × 0.5 m with four replications. LAI at the ground level (LAI-cept) was determined with AccuPAR LP-80 ceptometer (using effective plant area index $L_e = \Omega L$ where Ω refers to a clumping index resulting from the non-random distribution of canopy elements). The remote sensing-based LAI (LAI-sat) was obtained from platform Weekeo based on a neural network that utilizes the surface reflectance of Sentinel-2A bands. The relationships between the in situ LAI-cept and biomass and the LAI-sat data were determined. The correlations were tested using the Pearson's *r* coefficient in the R statistical environment and modelled using simple linear regression with confidence interval displayed around the regression line (Wickham, 2016).

Results

The analysis has shown that there is a high correlation between all the in-situ grassland yields and the optical indicators of LAI. The correlation between LAI and FM is similarly for LAI-cept and for LAI-sat (r = 0.904 and r = 0.905, respectively). In the case of correlation between LAI and DM the LAI-cept is slightly better than LAI-sat (r = 0.936 and r = 0.904, respectively). In general our results indicate that linear relationships between LAI-sat or LAI-cept and the studied semi-natural grassland yield indicators are high. However, the scatter plots illustrating these relationships suggest that yield estimation using optical LAI indicators is most precise before the accumulation of semi-natural grassland biomass reaches ca. 1000 g m^{-2} of FM or 200 g m^{-2} of DM (Figure 1). All these threshold values are consistent with one another. Above these thresholds, the studied LAI indicators seem to be less responsive to the accumulation of semi-natural grassland biomass increase, which is indicated by the wider points dispersion and the weaker trend of increase in the plots. This is related to the change in the structure of aboveground biomass due to the transition from the vegetative to the generative growth stage in grasses and other plants. Another reason is foliage overlapping that makes some leaves invisible to the optical sensors. In such situation a combination of both, cover to mass can be used, like is commonly used in Australia at high and/or stoloniferous spreading pastures (Barnetson et al. 2021).

Discussion

Our study has shown that LAI-sat can be used to predict yield of semi-natural grassland yields in river valleys in decision support systems for its management, but the precision of this prediction can be further improved in future research. However, as reported by Reddersen et al. (2014), models for predicting biomass of extensively managed grassland using exclusive LAI were barely suited to predict biomass accurately, but can be improved significantly when combined with waveband selected common vegetation indices. We further propose that for tall and dense swards, the relationship between the yield and LAI-sat is modelled using a two-segment regression line (Muggeo, 2008), with the first segment steeper than the second one, and the breakpoint (yield indicator value where the two segments are connected) located near the above-mentioned threshold values. Interesting findings regarding pasture yield estimation were presented by Barnetson et al. (2021), suggesting the need to measure the biomass structure, i.e. height or density. In the case of coastal grassland and inland woodland pasture, they developed deep learning predictive models of pasture yield from field measurements and both remotely piloted aircraft systems and satellite imagery.

The accuracy between LAI and FM or DM was slightly higher for LAI-cept than for LAI-sat, but the correlation between the in-situ grassland yield and the optical indicators of LAI was very high ($r > 0.90$). This result confirms the findings of other authors, e.g. Klingler et al. (2020) or Dąbrowska-Zielińska et al. (2024), who generally observed a significant influence of the seasonal changes of the canopy structure and morphology on the estimation accuracy. The optical remote sensing LAI applied for semi-natural grassland yields prediction is an efficient method that can be used to monitor the productivity of grass communities located in riparian areas of river valleys. This can help in planning for agricultural practices, can be an efficient tool in decision support system of semi-natural grassland management, and offsetting financial risks on large scales. The remote sensing-base LAI estimated by using Sentinel-2 is also of major importance for optimal semi-natural grassland growth modelling.

Cumulative ground cover maintenance: what does it tell us about the grazing landscape and its management?

Graz FP[1]; Beutel TS[1]

[1]Department of Primary Industries, 25 Yeppoon Road, Parkhurst (Rockhampton) 4701, QLD

Key words: Ground cover; grazing; land condition

Abstract

Two key challenges in rangeland management are determining the sustainability of management practices and the cumulative impact of those practices on the condition / health / productivity of the managed landscape. To this end remotely sensed cover products have been widely used in recent decades as there are no alternative products with a comparable spatiotemporal coverage and resolution.

We trialled a new approach to remotely assess land condition and management sustainability using ground cover data. The method first benchmarks Spring ground cover per pixel against local ground cover values within the land type (regional comparison (RC)). RC is a useful ground cover benchmark because it accounts for impact of land type and rainfall history on ground cover at any site. We then model Spring RC values based on the RC value of the previous Spring and recency of fire (a driver of ground cover not well accounted for by RC). We interpret the predicted quantile of any model prediction (GCM) as an index of how well the RC value has been maintained over that year at the site.

If annual GCM values do indicate how well ground cover has been maintained within the year, it is possible that long term consistency in GCM values (high or low) may highlight the broader sustainability of the management system (e.g. management that maintains ground cover probably also limits erosion and promotes desirable pasture species). Furthermore, more sustainable management systems might indicate places of high and/or improving land condition. This poster explains how the GCM layers were developed and tests the idea that they could be a useful tool to map both the historical sustainability of management systems as well as their impacts on land condition.

Introduction

Two key challenges in rangeland management are determining the sustainability of management practices and understanding their cumulative impact on the condition / health / productivity of the managed landscape. In the Australian rangelands, the sustainability of grazing management practices impacts the landscape through changes in the composition and amount of ground cover present in the landscape. Consequently, remotely sensed ground cover (GC) data – green and non-green cover such as described by the Queensland Government & Joint Remote Sensing Research Program (2022) – has been used widely in recent decades to track landscape change. Management practice impacts other landscape outcomes as well (e.g. erosion, weed infestation) but there are no analogous remotely sensed datasets with a comparable spatiotemporal coverage and resolution as the existing GC archives to track these outcomes remotely.

One potential geographic identifier of sustainable management practices in grazing land is the consistent maintenance of GC at or above expected (taking into account recent climate and land type) (Beutel & Graz, 2022). If this was the case, and it was possible to quantify and map how well GC was maintained per year, then the cumulative quantum of maintenance could also be mapped and might well indicate the longer-term sustainability of management at any location, at least as far as GC levels are concerned.

Beutel and Graz (2022) trialled this approach by modelling annual change in GC across a section of the Queensland rangelands. That study modelled annual change in ground cover using a large multivariate model and then used the quantile of observed change for any pixel (hereafter GCM: ground cover maintenance score) within its modelled prediction interval to benchmark the observed change for that year. They concluded that cumulative GCM (CGCM) values had some correlation with grazing land condition (Chilcott et al., 2003), but that the GCM model needed to incorporate the impact of fire history and better predict change in GC to fully test the relationship between land condition and CGCM.

Objective

In this study, we developed and tested an alternative approach to generating GCM map layers. The new method models annual change pixel regional comparison (RC) values rather than change in raw ground cover values. Regional comparison values (Beutel et al., 2021) take into account rainfall and land type so were seen as a potentially better target to model than raw GC. The new layer development also incorporates fire recency into GCM calculations. We describe the development of these new GCM layers and their relationship with land condition at a set of sites in Queensland.

Methods and results

Study area

The study area encompasses the Burdekin, Fitzroy and Burnett-Mary catchments, covering around 350,700km^2 in Queensland, Australia (Figure 1). Rainfall in the area is highly variable - between 500 and 1,300 mm annually across the region. Around 175 different land types have been identified in the study area (Department of Agriculture and Fisheries, 2022), many of which are subject to intermittent burning.

Data processing

Our method generated two raster data sets to align with the 30x30m Landsat imagery. We first built seasonal regional comparison (RC) rasters for the study area for each Spring (2014-2023). These images map ground cover quantiles (0 to 100) by comparing cover in each pixel to other pixels in the same land type (Department of Agriculture and Fisheries (2022)) within a 20 km radius. Higher RC pixel values indicate relatively higher levels of ground cover within the land type and local area. Each RC image is thus a point-in-time evaluation of ground cover given the land type, as well as recent local climate and management histories.

We generated a corresponding second set of GCM images to rank annual change in RC values. A quantile random forest model was used to predict RC per pixel for each Spring from two variables: the previous Spring's RC value and the number of months since the most recently mapped fire (fire recency). Fire recency data were based on Collett (2021) and van den Berg (2021), and were included because Beutel and Graz (2022) showed the dramatic impact of fire recency on their GCM images. The model accounted for 51% of the variance in annual RC change, of which $<2\%$ was contributed by inclusion of the fire recency data. The resulting GCM image values range from 0 to 100 and we interpret them as indicative of how well ground cover was maintained after fire recency and starting RC values were accounted for.

Analysis

Assuming that each annual GCM image reflects how well ground cover was maintained in that year, we tested whether cumulative GCM values might correspond to longer term management outcomes. We built cumulative GCM images (CGCM) by averaging annual values per pixel for the period 2015-2023. We then extracted mean CGCM pixel values at 2,220 sites where land condition had been assessed in 90x90m plots between 2021 and 2023, and compared the mean CGCM values allocated to different land condition classes. The boxplot of CGCM scores for each land condition class is shown below (Figure 2). It shows that CGCM differentiates the D (very poor) condition class quite well from others, but better condition classes, particularly A and B, are very similar in terms of CGCM scores.

Discussion

This paper outlines the development of a new version of GCM mapping. This version was built using a different approach to Beutel and Graz (2022); GCM values were based here on the regional comparison methodology rather than modelling GC in a complex multivariate modelling process. This new work also considered fire recency, which was absent from the original analysis.

Our test of whether CGCM values might predict land condition showed CGCM has some potential for mapping D condition but does not discriminate other condition classes very well. D condition sites are typically the easiest to identify remotely because they most often have very low GC levels. As such, it is not surprising that D condition sites were easiest to discriminate using CGCM. The approach may have worked better on other condition classes had we used a longer cumulative period than 2015-2023 or had our model accounted for more of the variance in annual RC change. It is possible too though that CGCM can't discriminate higher land condition classes. Higher classes of condition result more often from change in vegetation composition than GC, and since CGCM is derived from GC imagery, it may lack sufficient capacity to indicate changes in composition.

In this work we were interested in the idea that CGCM might be a tool to map the longer-term sustainability of management practices. We used land condition as a surrogate for management outcomes because these data were available to us. In doing this though we implicitly assumed that more sustainable management systems should have better land condition. This is not always true though. For example, where the management system has recently changed (e.g. through succession or sale) current land condition is likely more due to previous than current management practices, and very poor condition (D) is resistant to most management changes (Chilcott et al. 2003) so may persist through multiple managers and management systems. In summary, land condition may have some relationship to CGCM at the poorer end of the land condition spectrum, but it may not be the best surrogate to test the connection between CGCM and the sustainability of recent management.

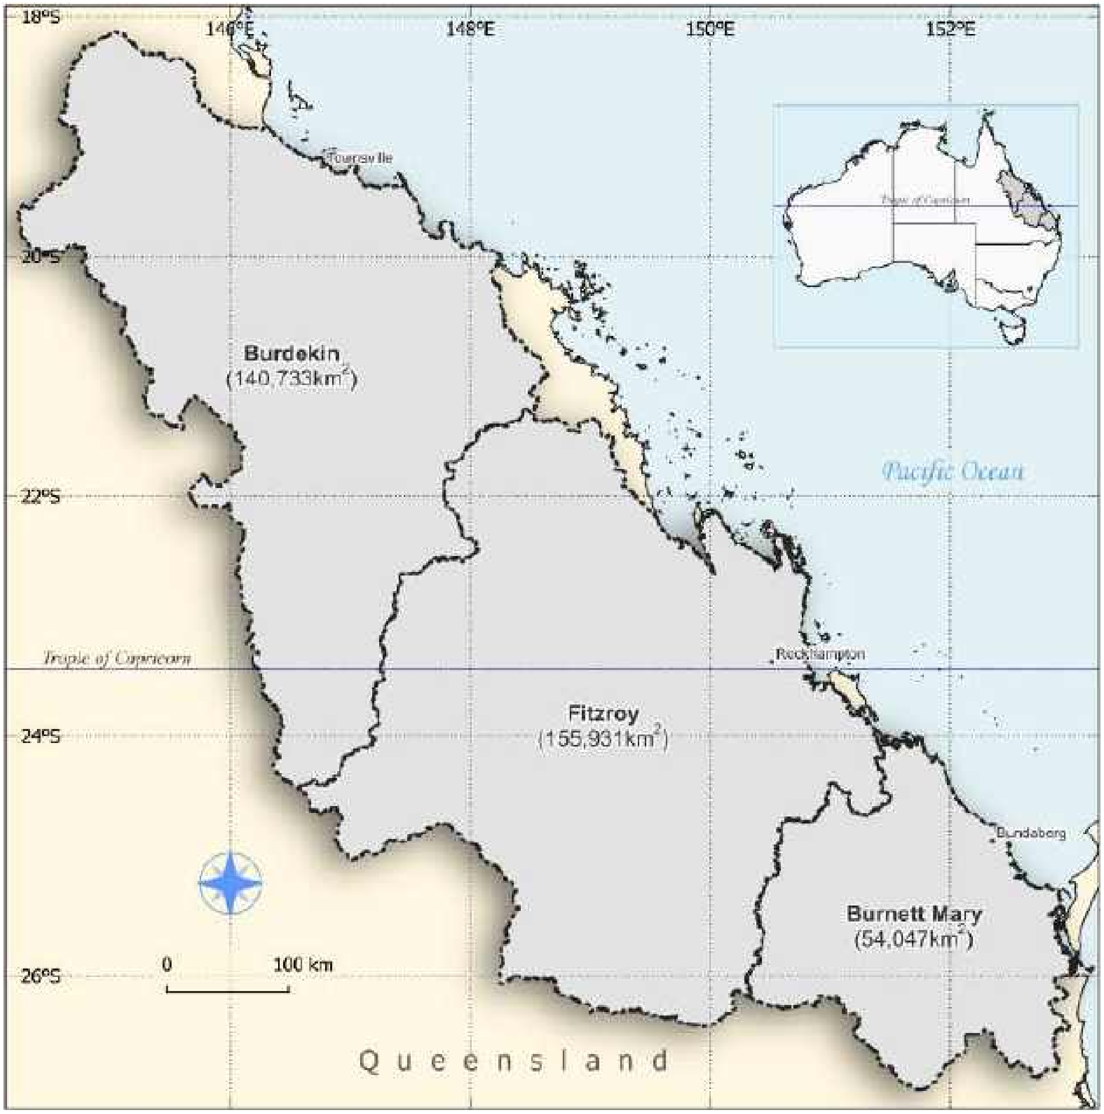

Figure 1. Location of the study area.

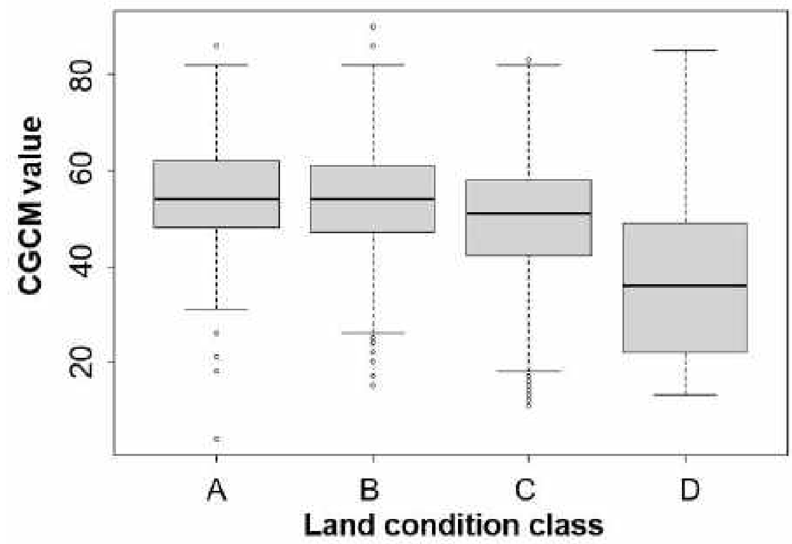

Figure 2. Cumulative (mean) GCM values for different land condition classes on 2220 land condition assessment sites in the study area.

Conclusion

This work is part of a larger project investigating different ways to model Queensland's rangeland health and productivity. This test of the GCM approach suggests that the method may not predict land condition reliably, but we plan several other uses and evaluations of the GCM methodology and products.

There's an app for that: development of a decision support tool for the management of Twolined Spittlebug on Hawaii rangelands

[T]horne, MS; [2]Wright, M; [3]Wilson, S; [4]Peck, D; [5]Oshiro, M

Key words: Rangelands; Pest Management; Decision Support Tools

Abstract

Twolined spittlebug (TLSB), *Prosapia bicincta*, was detected in Hawaii in 2016 where it had damaged over 2,000 acres of rangeland. Research revealed that TLSB expanded its range to over 178,000 acres in approximately six generations. In highly infested areas, TLSB resulted in nearly 100% die back of key range grasses including Kikuyu (*Pennisetum clandestinum*) and pangola (*Digitaria eriantha*) grasses when nymph densities exceeded 50/m^2. The loss of these important forages provided entry for the establishment of invasive plants including Pamakani (*Eupatorium adenophorum*), wild blackberry (*Rubus* spp.), and fireweed (*Senecio madagascariensis*) among others. These losses forced livestock producers to reduce stocking rates resulting in significant economic losses. Work on a smartphone application to identify, report, and facilitate management of the TLSB started in 2020. The app has four main features. First, an information guide provides an overview of TLSB biology and ecology. Next, the app provides a tool to help users identify TLSB in the field and distinguish it from other, non-pest species. A third tool allows users to report sightings of TLSB. Reports include a geo-referenced picture and basic details about the habitat and geographical location of the pest. The reported data is then captured in a database and displayed on a web-based mapping tool. Users have the option to enter data on TLSB population density and provide estimates on spatial extent and observed damage in their report. Data on TLSB populations is determined by following sampling protocols provided in the fourth tool. This tool allows users to determine the size of the TLSB population, and then, based on the potential damage threshold calculated, select from a series of integrated pest management decisions. It is anticipated that this app will facilitate tracking and documenting the spread of the pest and lead to better pest management decisions for rangeland managers.

Introduction

Twolined spittlebug (TLSB), *Prosapia bicincta* (Say), a pasture and turfgrass pest native to southeastern United States (Shortman et al. 2002, Thompson and Carvalho 2016), was detected in the South Kona district of Hawai´i Island in 2016 (Wilson et al. 2023). The pest negatively impacts rangelands by feeding on important forage grasses (Byers and Wells 1966, Shortman et al. 2002, Wilson et al. 2024). Our research found that between 2017 and 2020 the pest rapidly expanded its range at rate of over 14,000 ha per year and by the end of 2021 occupied over 72,183 ha across the South Kona district in just six generations (Wilson et al. 2023).
